Disclaimer

The data, examples and diagrams in this manual are included solely for the concept or product description and are not to be deemed as a statement of guaranteed properties. All persons responsible for applying the equipment addressed in this manual must satisfy themselves that each intended application is suitable and acceptable, including that any applicable safety or other operational requirements are complied with. In particular, any risks in applications where a system failure and/or product failure would create a risk for harm to property or persons (including but not limited to personal injuries or death) shall be the sole responsibility of the person or entity applying the equipment, and those so responsible are hereby requested to ensure that all measures are taken to exclude or mitigate such risks.

This document has been carefully checked by ABB but deviations cannot be completely ruled out. In case any errors are detected, the reader is kindly requested to notify the manufacturer. Other than under explicit contractual commitments, in no event shall ABB be responsible or liable for any loss or damage resulting from the use of this manual or the application of the equipment.
Conformity

This product complies with the directive of the Council of the European Communities on the approximation of the laws of the Member States relating to electromagnetic compatibility (EMC Directive 2004/108/EC) and concerning electrical equipment for use within specified voltage limits (Low-voltage directive 2006/95/EC). This conformity is the result of tests conducted by ABB in accordance with the product standards EN 50263 and EN 60255-26 for the EMC directive, and with the product standards EN 60255-6 and EN 60255-27 for the low voltage directive. The relay is designed in accordance with the international standards of the IEC 60255 series and ANSI C37.90.

Section 1 Introduction

1.1 This manual

The technical manual contains application and functionality descriptions and lists function blocks, logic diagrams, input and output signals, setting parameters and technical data sorted per function. The manual can be used as a technical reference during the engineering phase, installation and commissioning phase, and during normal service.

1.2 Intended audience

This manual addresses system engineers and installation and commissioning personnel, who use technical data during engineering, installation and commissioning, and in normal service.

The system engineer must have a thorough knowledge of protection systems, protection equipment, protection functions and the configured functional logic in the relays. The installation and commissioning personnel must have a basic knowledge in handling electronic equipment.
The engineering manual contains instructions on how to engineer the relays using the different tools in PCM600. The manual provides instructions on how to set up a PCM600 project and insert relays to the project structure. The manual also recommends a sequence for engineering of protection and control functions, LHMI functions as well as communication engineering for IEC 61850 and DNP3.

The installation manual contains instructions on how to install the relay. The manual provides procedures for mechanical and electrical installation. The chapters are organized in chronological order in which the relay should be installed.

The operation manual contains instructions on how to operate the relay once it has been commissioned. The manual provides instructions for monitoring, controlling and setting the relay. The manual also describes how to identify disturbances and how to view calculated and measured power grid data to determine the cause of a fault.

The application manual contains application descriptions and setting guidelines sorted per function. The manual can be used to find out when and for what purpose a typical protection function can be used. The manual can also be used when calculating settings.

The technical manual contains application and functionality descriptions and lists function blocks, logic diagrams, input and output signals, setting parameters and technical data.
sorted per function. The manual can be used as a technical reference during the engineering phase, installation and commissioning phase, and during normal service.

The communication protocol manual describes a communication protocol supported by the relay. The manual concentrates on vendor-specific implementations. The point list manual describes the outlook and properties of the data points specific to the relay. The manual should be used in conjunction with the corresponding communication protocol manual.

1.3.3 Related documentation

1.4 Symbols and conventions

1.4.1 Safety indication symbols

The electrical warning icon indicates the presence of a hazard which could result in electrical shock.

The warning icon indicates the presence of a hazard which could result in personal injury.

The caution icon indicates important information or warning related to the concept discussed in the text. It might indicate the presence of a hazard which could result in corruption of software or damage to equipment or property.
Although warning hazards are related to personal injury, it should be understood that operation of damaged equipment could, under certain operational conditions, result in degraded process performance leading to personal injury or death. Therefore, comply fully with all warning and caution notices.

1.4.2 Manual conventions

Conventions used in relay manuals. A particular convention may not be used in this manual.

- Abbreviations and acronyms in this manual are spelled out in the glossary. The glossary also contains definitions of important terms.
- Push button navigation in the LHMI menu structure is presented by using the push button icons, for example:
  To navigate between the options, use \key{up} and \key{down}.
- HMI menu paths are presented in bold, for example:
  Select **Main menu > Settings**.
- LHMI messages are shown in Courier font, for example:
  To save the changes in non-volatile memory, select **Yes** and press \key{ok}.
- Parameter names are shown in italics, for example:
  The function can be enabled and disabled with the **Operation** setting.
- Parameter values are indicated with quotation marks, for example:
  The corresponding parameter values are “Enabled” and “Disabled”.
- Relay input/output messages and monitored data names are shown in Courier font, for example:
  When the function picks up, the **PICKUP** output is set to TRUE.
- Dimensions are provided both in inches and mm. If it is not specifically mentioned then the dimension is in mm.
- Analog inputs to protection functions are shown in the technical manual for clarity however these inputs and connections do not appear in the application logic. The connection of these analog signals is fixed internally to the corresponding function blocks and cannot be altered by users.
1.4.3 Functions, codes and symbols

All available functions are listed in the table. All of them may not be applicable to all products.

Section 2  RER620 overview

2.1  Overview

RER620 is a product family of relays designed for protection, control, measurement and supervision of utility substations and industrial switchgear and equipment. The design of the relays has been guided by the IEC 61850 standard for communication and interoperability of substation automation devices.

The relays feature draw-out-type design with a variety of mounting methods, compact size and ease of use. Depending on the product, optional functionality is available at the time of order for both software and hardware, for example, autoreclosure and additional I/Os.

The RER620 relays support a range of communication protocols including IEC 61850 with GOOSE messaging, Modbus®, DNP3, PG&E 2179 and IEC 101/104.

2.1.2  PCM600 and relay connectivity package version

- Protection and Control Relay Manager PCM600 2.7 or later versions of PCM600
- Relay Connectivity Package RER620 Ver. 1.3 or later

Download connectivity packages from the ABB web site http://www.abb.com/substationautomation
2.2 Local HMI

![LHMI Image]

The LHMI of the relay contains the following elements:

- Display
- Buttons
- LED indicators
- Communication port

The LHMI is used for setting, monitoring and controlling.

2.2.1 LCD

The LHMI includes a graphical LCD that supports two character sizes. The character size depends on the selected language.
### Table 2: Characters and rows on the view

<table>
<thead>
<tr>
<th>Character size</th>
<th>Rows in view</th>
<th>Characters on row</th>
</tr>
</thead>
<tbody>

<td>Large, variable width (13x14 pixels)</td>
<td>4 rows</td>
<td>min 8</td>
</tr>
<tr>
<td></td>
<td>8 rows with large screen</td>
<td></td>
</tr>
</tbody>
</table>

The display view is divided into four basic areas.

![Display layout](image)

**Figure 4: Display layout**

1. Header
2. Icon
3. Content
4. Scroll bar (displayed when needed)

#### 2.2.2 LEDs

The LHMI includes three protection indicators above the display: Normal, Pickup and Trip.

There are also 11 matrix programmable alarm LEDs on front of the LHMI. The LEDs can be configured with PCM600 and the operation mode can be selected with the LHMI, WHMI or PCM600.

There are two additional LEDs which are embedded into the control buttons and . They represent the status of the circuit breaker.

#### 2.2.3 Keypad

The LHMI keypad contains push-buttons which are used to navigate in different views or menus. With the push-buttons you can give open or close commands to one primary object, for example, a circuit breaker, disconnector or switch. The push-buttons are also used to acknowledge alarms, reset indications, provide help and switch between local and remote control mode.
Figure 5: LHMI keypad with object control, navigation and command push-buttons and RJ-45 communication port

2.3 Web HMI

The WHMI enables the user to access the relay via a web browser. The supported web browser versions are Internet Explorer 9.0, 10.0 and 11.0.

WHMI is enabled by default.

WHMI offers several functions.

- Alarm indications and event lists
- System supervision
- Parameter settings
- Measurement display
- Oscillographic records
- Phasor diagram

The menu tree structure on the WHMI is almost identical to the one on the LHMI.
The WHMI can be accessed locally and remotely.

- Locally by connecting your laptop to the relay via the front communication port.
- Remotely over LAN/WAN.

2.4 Authorization

The user categories have been predefined for the LHMI and the WHMI, each with different rights and default passwords.

The default passwords can be changed with Administrator user rights.
User authorization is disabled by default but WHMI always uses authorization.

<table>

| OPERATOR  | • Selecting remote or local state with (only locally)  
• Changing setting groups  
• Controlling  
• Clearing alarm and indication LEDs and textual indications |
| ENGINEER  | • Changing settings  
• Clearing event list  
• Clearing DFRs  
• Changing system settings such as IP address, serial baud rate or DFR settings  
• Setting the relay to test mode  
• Selecting language |
| ADMINISTRATOR | • All listed above  
• Changing password  
• Factory default activation |

For user authorization for PCM600, see PCM600 documentation.

2.5 Communication

The relay supports different communication protocols: IEC 61850, Modbus® and DNP 3.0 Level 2, IEC 104- all using TCP/IP. DNP3, PG&E 2179, IEC101 and Modbus are supported through serial communication. Operational information and controls are available through these protocols.

The IEC 61850 communication implementation supports all monitoring and control functions. Additionally, parameter setting and DFR records can be accessed using the IEC 61850 protocol. Oscillographic files are available to any Ethernet-based application in the standard COMTRADE format. Further, the relay can send and receive binary signals from other relays (so called horizontal communication) using the IEC61850-8-1 GOOSE profile, where the highest performance class with a total transmission time of 3 ms is supported. The relay meets the GOOSE performance requirements for tripping applications in distribution substations, as defined by the IEC 61850 standard. The relay can simultaneously report events to five different clients on the station bus.

All communication connectors, except for the front port connector, are placed on integrated optional communication modules. The relay can be connected to Ethernet-based communication systems via the RJ-45 connector (100BASE-TX) or the fiber-optic LC connector (100BASE-FX).

### DST Settings

DST settings depends on the time sync source. For example:

1. If time sync source is set to local time, we should set "Local time offset" and "DST offset" to 0, the system time will be the same as the sync source.

2. If the time sync source is set to UTC, we can set the following values,
   - Local time offset = -300 (for Eastern time zone)
   - DST on time = 2:00
3. If no time sync source, we can set the following DST values,
   DST on time = 2:00
   DST on date = 03/08
   DST on day = Sun
   DST offset = 60 min
   DST off time = 2:00
   DST off date = 11/01
   DST off day = Sun

   These settings will take care of all the DST time changes automatically, no need to adjust every year.

3.2 Self-supervision

The relay's extensive self-supervision system continuously supervises the software and the electronics. It handles run-time fault situation and informs the user about a fault via the LHMI and through the communications channels.

There are two types of fault indications.

- Internal faults
- Warnings

3.2.1 Internal faults

When a relay internal fault is detected, the green Normal LED begins to flash and the self-supervision output contact is activated.

Internal fault indications have the highest priority on the LHMI. None of the other LHMI indications can override the internal fault indication.

An indication about the fault is shown as a message on the LHMI. The text Internal Fault with an additional text message, a code, date and time, is shown to indicate the fault type.

Different actions are taken depending on the severity of the fault. The relay tries to eliminate the fault by restarting. After the fault is found to be permanent, the relay stays in internal fault mode. All other output contacts are released and locked for the internal fault. The relay continues to perform internal tests during the fault situation.

If an internal fault disappears, the green Normal LED stops flashing and the relay returns to the normal service state. The fault indication message remains on the LCD until manually cleared.

The self-supervision signal output operates on the closed circuit principle. Under normal conditions the relay is energized and the contact gap 3-5 in slot X100 is closed. If the auxiliary power supply fail or an internal fault is detected, the contact gap 3-5 is opened.
Figure 7: Output contact

The internal fault code indicates the type of internal relay fault. When a fault appears, record the code so that it can be reported to ABB customer service.

For further information on internal fault indications, see the operation manual.

3.2.2 Warnings

In case of a warning, the relay continues to operate except for those protection functions possibly affected by the fault, and the green Normal LED remains lit as during normal operation.

Warnings are indicated with the text Warning and is additionally provided with the name of the warning, a numeric code, and the date and time on the LHMI. The fault indication message can be manually cleared.

If a fault appears, record the name and code so that it can be provided to ABB customer service.

</tbody>
</table>

For further information on warning indications, see the operation manual.
3.3 **LED indication control**

The relay includes a global conditioning function LEDPTRC that is used with the protection indication LEDs.

LED indication control should never be used for tripping purposes. There is a separate trip logic function TRPPTRC available in the relay configuration.

LED indication control is pre configured in such a way that all the protection functions general pickup and trip signals are combined with this function (available as output signals `OUT_PICKUP` and `OUT_TRIP`). These signals are always internally connected to Pickup and Trip LEDs. LEDPTRC collects and combines phase information from different protection functions (available as output signals `OUT_PU_A`/`B`/`C` and `OUT_TRP_A`/`B`/`C`). There is also combined ground fault information collected from all the ground fault functions available in the relay configuration (available as output signals `OUT_PU_NEUT` and `OUT_TRP_NEUT`).

3.4 **Time synchronization**

The relay has an internal real-time clock which can be either free-running or synchronized from an external source. The real-time clock is used for time stamping events, recorded data and disturbance recordings.

The relay is provided with a 48-hour capacitor back-up that enables the real-time clock to keep time in case of an auxiliary power failure.

Setting *Synch Source* determines the method how the real-time clock is synchronized. If set to “None”, the clock is free-running and the settings *Date* and *Time* can be used to set the time manually. Other setting values activate a communication protocol that provides the time synchronization. Only one synchronization method can be active at a time but SNTP provides time master redundancy.

The relay supports SNTP, IRIG-B, DNP3 and Modbus to update the real-time clock. IRIG-B with GPS provides the best accuracy.

- When Modbus TCP or DNP3 over TCP/IP is used, SNTP time synchronization should be used for better synchronization accuracy.

- DNP3 can be used as a time synchronization source.

- When the SNTP server IP setting is changed, the relay must be rebooted to activate the new IP address. The SNTP server IP settings are normally defined in the engineering phase via the SCL file.
The relay can use one of two SNTP servers, the primary or the secondary server. The primary server is mainly in use, whereas the secondary server is used if the primary server cannot be reached. While using the secondary SNTP server, the relay tries to switch back to the primary server on every third SNTP request attempt. If both the SNTP servers are offline, event time stamps have the time invalid status. The time is requested from the SNTP server every 60 seconds.

IRIG-B time synchronization requires the IRIG-B format B000/B001 with IEEE-1344 extensions. The synchronization time can be either UTC time or local time. As no reboot is necessary, the time synchronization starts immediately after the IRIG-B sync source is selected and the IRIG-B signal source is connected.

ABB has tested the IRIG-B with the following clock masters:

- Tekron TTM01 GPS clock with IRIG-B output
- Meinberg TCG511 controlled by GPS167
- Datum ET6000L
- Arbiter Systems 1088B

IRIG-B time synchronization requires a COM card with an IRIG-B input. Available only with some models.

### 3.5 Parameter setting groups

There are four relay variant specific setting groups. For each setting group, the parameter setting can be made independently.

The active setting group can be changed by parameter (setting groups 1...6) or via binary input (setting groups 1...6), if a binary input is enabled for it.

To use a binary input to change setting groups use ACT (Application Configuration Tool) to program a Hardware Channel Binary input to the Protection block.

<table>
<thead>
<tr>
<th>BI state</th>
<th>Active setting group</th>
<th>Active setting group</th>
</tr>
</thead>
<tbody>
<tr>
<td>OFF</td>
<td>1</td>
<td></td>
</tr>
<tr>
<td>ON</td>
<td>2</td>
<td></td>
</tr>
</tbody>
</table>

The setting group parameter is overridden when a binary input is used for changing the active setting group.
3.6 Recorded data

The relay has the capacity to store the records of 32 latest fault events. The records enable the user to analyze the 32 most recent power system events. Each fault record (FLTMSTA) is marked with an up-counting fault number. Slot fault record 1 always contains the newest record, and fault record 32 the oldest. The time stamp is taken from the beginning of the fault.

The fault recording period begins from the pickup event of any protection function and ends if any protection function trips or the pickup(s) is restored before the trip event. The type of fault that triggers the fault recording is selected with the setting parameter Trig mode. When “From all faults” is selected, all types of detected faults trigger a new fault recording. When “From trip” is selected, only faults that cause an trip event trigger a new fault recording. Finally when From only pickup is selected, only faults that cause a protection function restoring before the actual trip signal are recorded.

Fault recorder (FLR) collects some minimum and maximum current and voltage values during the recording period. DFT, RMS or Peak-to-Peak can be set as the generic measuring mode with setting parameter Measurement mode. The recording of the maximum and minimum phase currents, maximum ground current and maximum ground voltage is affected by the selected measuring mode and the maximum current and voltage values are still collected 50 ms after the recording period is closed. In addition, the maximum demand current is separately recorded with time stamp.

Fault recorder also provides Operation parameter that can be used for setting the recorder into Enable/Disable and BLOCK input that can be used for blocking the recording triggering by using logic, for example during the auto-reclosing sequence. The recorded data can be separately cleared with parameters in the Clear menu.

The data recorded depend on the product and the standard configuration.

---

<td>0.00...100.00</td>
<td>%</td>
<td>67/50P-1 Pickup duration</td>
</tr>
</tbody>
</table>
3.7 Non-volatile memory

In addition to the setting values, the relay can store some data in the non-volatile memory.

- Up to 512 events are stored. The stored events are visible in LHMI and WHMI only.
- Recorded data
  - Fault records
  - Maximum demands
- Circuit breaker condition monitoring
- Latched alarm and trip LEDs' status
- Trip circuit lockout
- Counter values

3.8 Binary input

3.8.1 Binary input filter time

The filter time eliminates debounces and short disturbances on a binary input. The filter time is set for each binary input of the relay.
At the beginning, the input signal is at the high state, the short low state is filtered and no input state change is detected. The low state starting from the time $t_0$ exceeds the filter time, which means that the change in the input state is detected and the time tag attached to the input change is $t_0$. The high state starting from $t_1$ is detected and the time tag $t_1$ is attached.

Each binary input has a filter time parameter $\text{Input # filter}$, where # is the number of the binary input of the module in question (for example $\text{Input 1 filter}$).

### Table 36: Input filter parameter values

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Values</th>
<th>Default</th>
</tr>
</thead>
<tbody>
<tr>
<td>$\text{Input # filter}$</td>
<td>1...15000 ms</td>
<td>5 ms</td>
</tr>
</tbody>
</table>

#### 3.8.2 Binary input inversion

The parameter $\text{Input # invert}$ is used to invert a binary input.

### Table 37: Binary input states

<table>
<thead>
<tr>
<th>Control voltage</th>
<th>Input # invert</th>
<th>State of binary input</th>
</tr>
</thead>
<tbody>
<tr>
<td>No</td>
<td>0</td>
<td>False (0)</td>
</tr>
<tr>
<td>Yes</td>
<td>0</td>
<td>True (1)</td>
</tr>
<tr>
<td>No</td>
<td>1</td>
<td>True (0)</td>
</tr>
<tr>
<td>Yes</td>
<td>1</td>
<td>False (0)</td>
</tr>
</tbody>
</table>

When a binary input is inverted, the state of the input is TRUE (1) when no control voltage is applied to its terminals. Accordingly, the input state is FALSE (0) when a control voltage is applied to the terminals of the binary input.
3.8.3 Oscillation suppression

Oscillation suppression is used to reduce the load from the system when a binary input starts oscillating. A binary input is regarded as oscillating if the number of valid state changes (= number of events after filtering) during one second is equal to or greater than the set oscillation level value. During oscillation, the binary input is blocked (the status is invalid) and an event is generated. The state of the input will not change when it is blocked, that is, its state depends on the condition before blocking.

The binary input is regarded as non-oscillating if the number of valid state changes during one second is less than the set oscillation level value minus the set oscillation hysteresis value. Note that the oscillation hysteresis must be set lower than the oscillation level to enable the input to be restored from oscillation. When the input returns to a non-oscillating state, the binary input is deblocked (the status is valid) and an event is generated.

3.9 GOOSE function blocks

GOOSE function blocks are used for connecting incoming GOOSE data to application. They support BOOLEAN, Dbpos, Enum, FLOAT32, INT8 and INT32 data types.

Common signals

The VALID output indicates the validity of received GOOSE data, which means in case of valid, that the GOOSE communication is working and received data quality bits (if configured) indicate good process data. Invalid status is caused either by bad data quality bits or GOOSE communication failure. See IEC 61850 engineering guide for details.

The OUT output passes the received GOOSE value for the application. Default value (0) is used if VALID output indicates invalid status. The IN input is defined in the GOOSE configuration and can always be seen in SMT sheet.

Settings

The GOOSE function blocks do not have any parameters available in LHMI or PCM600.
3.9.1 GOOSERCV_BIN function block

3.9.5 GOOSERCV_INTL function block

3.9.5.1 Function block

![Figure 13: Function block](image)

3.9.5.2 Functionality

The GOOSERCV_INTL function is used to connect the GOOSE double binary input to the application and extracting single binary position signals from the double binary position signal.

The OP output signal indicates that the position is open. Default value (0) is used if VALID output indicates invalid status.
The CL output signal indicates that the position is closed. Default value (0) is used if VALID output indicates invalid status.

The OK output signal indicates that the position is neither in faulty or intermediate state. The default value (0) is used if VALID output indicates invalid status.

### 3.9.6 GOOSERCV_CMV function block

#### 3.9.6.1 Function block

![function block](image)

#### 3.9.6.2 Functionality

The GOOSERCV_CMV function is used to connect GOOSE measured value inputs to the application. The MAG_IN (amplitude) and ANG_IN (angle) inputs are defined in the GOOSE configuration (PCM600).

The MAG output passes the received GOOSE (amplitude) value for the application. Default value (0) is used if VALID output indicates invalid status.

The ANG output passes the received GOOSE (angle) value for the application. Default value (0) is used if VALID output indicates invalid status.

3.10 Type conversion function blocks

3.10.1 QTY_GOOD function block

3.10.1.1 Function block

3.10.1.2 Functionality
The QTY_GOOD function block evaluates the quality bits of the input signal and passes it as a Boolean signal for the application.

The IN input can be connected to any logic application signal (logic function output, binary input, application function output or received GOOSE signal). Due to application logic quality bit propagation, each (simple and even combined) signal has quality which can be evaluated.

The OUT output indicates quality good of the input signal. Input signals that have no quality bits set or only test bit is set, will indicate quality good status.
3.10.1.3 Signals

</tbody>
</table>

3.10.2 QTY_BAD function block

3.10.2.1 Function block

![Function block diagram]

Figure 18: Function block

3.10.2.2 Functionality

The QTY_BAD function block evaluates the quality bits of the input signal and passes it as a Boolean signal for the application.

The IN input can be connected to any logic application signal (logic function output, binary input, application function output or received GOOSE signal). Due to application logic quality bit propagation, each (simple and even combined) signal has quality which can be evaluated.

The OUT output indicates quality bad of the input signal. Input signals that have any other than test bit set, will indicate quality bad status.

3.10.2.3 Signals

3.10.3  T_HEALTH function block

3.10.3.1 Function block

```
T_HEALTH

IN1  OK
WARNING  ALARM
```

**Figure 19:** Function block

3.10.3.2 Functionality

The T_HEALTH function evaluates enumerated data of “Health” data attribute. This function block can only be used with GOOSE.

The IN input can be connected to GOOSERCV_ENUM function block, which is receiving the LD0.LLN0.Health.stVal data attribute sent by another protection relay.

The outputs OK, WARNING and ALARM are extracted from the enumerated input value. Only one of the outputs can be active at a time. In case the GOOSERCV_ENUM function block doesn't receive the value from the sending relay or it is invalid, the default value (0) is used and the ALARM is activated in the T_HEALTH function block.

3.10.4  T_F32_INT8 function block

```
T_F32_INT8

F32  INT8
```

**Figure 20:** Function block
3.10.4.1 Functionality

T_F32_INT8 is a type conversion function.

The function converts 32-bit floating type values to 8-bit integer type. The rounding operation is included. Output value saturates if the input value is below the minimum or above the maximum value.

<table>

3.10.4.2 Settings

The function does not have any parameters available in LHMI or Protection and Control relay Manager (PCM600).

3.11 Configurable logic blocks

3.11.1 Standard configurable logic blocks

3.11.1.1 OR function block

Function block

![Function block diagram]

Figure 21: Function blocks

3.11.1.2 Functionality

OR and OR6 are used to form general combinatory expressions with Boolean variables.
The output is activated when at least one input has the value TRUE. The default value of all inputs is FALSE, which makes it possible to use only the required number of inputs and leave the rest disconnected.

OR has two inputs and OR6 has six inputs.

The function does not have any parameters available in LHMI or Protection and Control Relay Manager (PCM600).

### 3.11.1.8 R_TRIG function block

#### Function block

- **CLK**
- **R_TRIG**
- **O**

*Figure 27: Function block*

### Functionality
R_Trig is used as a rising edge detector.

R_Trig detects the transition from FALSE to TRUE at the CLK input. When the rising edge is detected, the element assigns the output to TRUE. At the next execution round, the output is returned to FALSE despite the state of the input.
**3.11.1.9 F_TRIG function block**

Function block

![Function block]

**Functionality**

F_Trig is used as a falling edge detector.

The function detects the transition from TRUE to FALSE at the CLK input. When the falling edge is detected, the element assigns the Q output to TRUE. At the next execution round, the output is returned to FALSE despite the state of the input.

<td>POS</td>
<td></td>
<td>OK</td>
</tr>
</tbody>
</table>
```

Figure 29: Function blocks

**Functionality**

The circuit breaker position information can be communicated with the IEC 61850 GOOSE messages. The position information is a double binary data type which is fed to the POS input.

T_POS_CL and T_POS_OP are used for extracting the circuit breaker status information. Respectively, T_POS_OK is used to validate the intermediate or faulty breaker position.
### Signals

### Settings

The function does not have any parameters available in LHMI or Protection and Control Relay Manager (PCM600).
### 3.11.1.11 SR function block

#### Function block

![Function block diagram](image-url)

#### Functionality

The SR flip-flop output Q can be set or reset from the s or R inputs. s input has a higher priority over the R input. Output NOTQ is the negation of output Q.

![Information icon]
The statuses of outputs Q and NOTQ are not retained in the nonvolatile memory.

3.11.1.12 PH_ORD_IN block

Function block

![Function block diagram](image)

**Functionality**

Normally, the relay expects to receive voltages, currents and breaker positions in the order specified by the setting "Phase Rotation". In reality, transmission lines are needed to be transposed to ensure the line impedance to be as symmetrical as possible under normal condition. With the system setting "Phase Order Mode", the relay (RER620) can properly indicate phase measurement and protection function operations, but it does not have a default mean to recognize the breaker (pole) position order.

This function reorders physical pole position inputs based on the global General System "Phase Order Mode" setting value to the normal system phase order.

The phase order from actual pole position inputs could be any of possible six combinations like ABC, BAC, CAB etc. With this function and the phase order mode setting, the ACT logic does not need to be changed for different physical phase orders. The order of the inputs of this function must match the General System "Phase Order Mode" setting value. The outputs of the function are always in the normal phase order (ABC) and thus they can be connected to the phase order neutral function blocks like SCBXCBR, SDARRREC etc.

This function should be used in conjunction with the function PH_ORD_OUT.

**Signals**

The function does not have any parameters available in LHMI or Protection and Control Relay Manager (PCM600).
3.11.1.13 PH_ORD_OUT block

Function block

```
PH_ORD_OUT
A  OUT1
B  OUT2
C  OUT3
```

Functionality

Normally, the relay expects to receive voltages, currents and breaker positions in the order specified by the setting "Phase Rotation". In reality, transmission lines are needed to be transposed to ensure the line impedance to be as symmetrical as possible under normal condition. With the system setting "Phase Order Mode", the relay (RER620) can properly indicate phase measurement and protection function operations, and with help of the function block PH_ORD_IN (see the detail in section 3.11.1.12), all the related control functions such as SCBXCBR, SDARRREC etc. provide the system rotation setting based operations which need to be matched the physical breaker (pole) position order.

This function reorders physical phase the outputs based according to the Global System "Phase Rotation" setting.

The phase order from actual field outputs could be any of possible six combinations like ABC, BAC, CAB etc. With this function and the phase order mode setting, the ACT logic
does not need to be changed for different physical phase orders. The function receives inputs from control function blocks in the normal phase order (ABC) and provide outputs based on the actual field phase order combination. The order of the outputs of this function must match the General System "Phase Order Mode" setting value so that the equipment to be controlled can be properly operated.

This function should be used in conjunction with the function PH_ORD_IN.

**Signals**

**Table 95: PH_ORD_OUT Input signals**

<td>Output signal 3</td>
</tr>
</tbody>
</table>

**Settings**

The function does not have any parameters available in LHMI or Protection and Control Relay Manager (PCM600).

When the System "Phase Order Mode" Setting changed, the relay must be rebooted to activate the new setting and the above functions will detect correct phase order.

### 3.11.2 Local/remote control function block CONTROL

#### 3.11.2.1 Function block

![Function block diagram](image-url)

*Figure 33: Function block*
3.11.2.2 Functionality

Local/Remote control is by default realized through the R/L button on the front panel. The control via binary input can enabled by setting the value of the **LR control** setting to "Binary input".

The actual Local/Remote control state is evaluated by the priority scheme on the function block inputs. If more than one input is active, the input with the highest priority is selected.

The actual state is reflected on the CONTROL function outputs. Only one output is active at a time.

**Table 97: Truth table for CONTROL**

<table>
<thead>
<tr>
<th>Input</th>
<th>CTRL_LOC</th>
<th>CTRL_STA 1)</th>
<th>CTRL_REM</th>
<th>Output</th>
</tr>
</thead>
<tbody>
<tr>

<td>FALSE</td>
<td>FALSE</td>
<td>FALSE</td>
<td>FALSE</td>
<td>OFF = TRUE</td>
</tr>
</tbody>
</table>

1) If station authority is not in use, the **CTRL_STA** input is interpreted as **CTRL_REM**.

The station authority check based on the command originator category can be enabled by setting the value of the **Station authority** setting to "Station, Remote" (The command originator validation is performed only if the **LR control** setting is set to "Binary input"). The station authority check is not in use by default.

### 3.12 Factory settings restoration

In case of configuration data loss or any other file system error that prevents the relay from working properly, the whole file system can be restored to the original factory state. All default settings and configuration files stored in the factory are restored. For further information on restoring factory settings, see the operation manual.
Section 4 Protection functions

4.1 Current protection

4.1.1 Single-phase non-directional overcurrent protection 51P/50P

4.1.1.1 Identification

The three-phase overcurrent protection 51P/50P is used as one-phase, two-phase or three-phase non-directional overcurrent and short-circuit protection for feeders. The function picks up when the current exceeds the set limit. The trip time characteristics for low stage 51P and high stage 50P-1/2 can be selected to be either definite time (DT) or inverse definite minimum time (IDMT). The instantaneous stage 50P-3 always trips with the DT characteristic.

In the DT mode, the function trips after a predefined trip time and resets when the fault current disappears. The IDMT mode provides current-dependent timer characteristics.

The function contains a blocking functionality. It is possible to block function outputs, timers or the function itself, if desired.

4.1.1.4 Operation principle

The function can be enabled and disabled with the Operation setting. The corresponding parameter values are “Enable” and “Disable.”
The single-phase non-directional overcurrent protection function is used as one-phase and three-phase overcurrent and short circuit protection. The phase-tripping mode is selected with the Configuration setting Recloser type.

The operation in either tripping mode can be described by using a module diagram (see Figure 35). Some modules have different functionality depending on whether the function is in one-phase or three-phase tripping mode. All the blocks in the diagram are explained in the next sections.

![Figure 35: Functional module diagram. I_A, I_B and I_C represent phase currents.](image)

**Level detector**

The measured phase currents are compared phase-wise with the set Pickup value and, if enabled, the Pickup block value. If the measured value exceeds the set Pickup value, and is less than the Pickup block value, the level detector reports the pickup to the phase selection logic. If the ENA_MULT input is active, the Pickup value setting is multiplied by the Pickup value Mult setting.

Do not set the multiplier setting Pickup value Mult higher than necessary. If the value is too high, the function may not trip at all during an inrush followed by a fault, no matter how severe the fault is.

The relay does not accept the Pickup value or Pickup value Mult setting if the product of these settings exceeds the Pickup value setting range.
The pickup value multiplication is normally done when the inrush detection function (INR) is connected to the ENA_MULT input.

![Image: Pickup value behavior with ENA_MULT input activated]

**Figure 36: Pickup value behavior with ENA_MULT input activated**

**Phase selection logic**

This logic is only active in three-phase tripping mode. If the fault criteria are fulfilled in the level detector, the phase selection logic detects the phase or phases in which the measured current exceeds the setting. If the phase information matches the Num of pickup phases setting, the phase selection logic activates the timer module.

When in single-phase tripping mode, the Num of pickup phases setting has no affect on operation and the outputs of the level detector are passed directly to the corresponding timer module.

**Timer**

Once activated, the timer activates the PICKUP output. Depending on the value of the Operating curve type setting, the time characteristics are according to DT or IDMT. When the operation timer has reached the value of Trip delay time in the DT mode or the maximum value defined by the inverse time curve and the Time adder time has expired, the TRIP output is activated.
When the user programmable IDMT curve is selected, the operate time characteristics are defined by the parameters Curve parameter A, Curve parameter B, Curve parameter C, Curve parameter D and Curve parameter E.

If a drop-off situation happens, that is, a fault suddenly disappears before the trip delay is exceeded, the timer reset state is activated. The functionality of the timer in the reset state depends on the combination of the Operating curve type, Type of reset curve and Reset delay time settings. When the DT characteristic is selected, the reset timer runs until the set Reset delay time value is exceeded. When the IDMT curves are selected, the Type of reset curve setting can be set to “Immediate”, “Def time reset” or “Inverse reset”. The reset curve type “Immediate” causes an immediate reset. With the reset curve type “Def time reset”, the reset time depends on the Reset delay time setting. With the reset curve type “Inverse reset”, the reset time depends on the current during the drop-off situation. If the drop-off situation continues, the reset timer is reset and the PICKUP output is deactivated.

The “Inverse reset” selection is only supported with ANSI or user programmable types of the IDMT operating curves. If another operating curve type is selected, an immediate reset occurs during the drop-off situation.

The setting Time multiplier is used for scaling the IDMT trip and reset times.

The setting parameter Minimum trip time defines the minimum desired trip time for IDMT. The setting is applicable only when the IDMT curves are used.

The Minimum trip time setting should be used with great care because the operation time is according to the IDMT curve, but always at least the value of the Minimum operate time setting. For more information, see the General function block features section in this manual.

The timer calculates the pickup duration (PICKUP_DUR) value which indicates the percentual ratio of the pickup situation and the set trip time. The value is available through the Monitored data view.

**Blocking logic**

There are three operation modes in the blocking functionality. The operation modes are controlled by the BLOCK input and the global setting “Configuration/System/Blocking mode” which selects the blocking mode. The BLOCK input can be controlled by a binary input, a horizontal communication input or an internal signal of the relay program. The influence of the BLOCK signal activation is preselected with the global setting Blocking mode.

The Blocking mode setting has three blocking methods. In the “Freeze timers” mode, the trip timer is frozen to the prevailing value. In the “Block all” mode, the whole function is blocked and the timers are reset. the “Block TRIP output” mode, the function operates normally but the TRIP output is not activated.
4.1.1.5 Measurement modes

The function operates on four alternative measurement modes: “RMS”, “DFT”, “Peak-to-Peak” and “P-to-P + backup”. The measurement mode is selected with the setting Measurement mode.

<table>
<thead>
<tr>
<th>Measurement mode</th>
<th>Supported measurement modes</th>

<tr>
<td>DFT</td>
<td>x</td>
</tr>
<tr>
<td>Peak-to-Peak</td>
<td>x</td>
</tr>
<tr>
<td>P-to-P + backup</td>
<td></td>
</tr>
</tbody>
</table>

For a detailed description of the measurement modes, see the General function block features section in this manual.

4.1.1.6 Timer characteristics

51P/50P supports both DT and IDMT characteristics. The user can select the timer characteristics with the Operating curve type and Type of reset curve settings. When the DT characteristic is selected, it is only affected by the Trip delay time and Reset delay time settings.

The relay provides 16 IDMT characteristics curves, of which seven comply with the IEEE C37.112 and six with the IEC 60255-3 standard. Two curves follow the special characteristics of ABB praxis and are referred to as RI and RD. In addition to this, a user programmable curve can be used if none of the standard curves are applicable. The user can choose the DT characteristic by selecting the Operating curve type values “ANSI Def. Time” or “IEC Def. Time”. The functionality is identical in both cases.

The following characteristics, which comply with the list in the IEC 61850-7-4 specification, indicate the characteristics supported by different stages:

</tbody>
</table>

The Type of reset curve setting does not apply to 50P-3 or when the DT operation is selected. The reset is purely defined by the Reset delay time setting.

4.1.1.7 Application

51P/50P is used in several applications in the power system. The applications include but are not limited to:

50P-3 supports only definite time characteristic.

For a detailed description of timers, see the General function block features section in this manual.
Protection functions

- Selective overcurrent and short-circuit protection of feeders in distribution and subtransmission systems
- Backup overcurrent and short-circuit protection of power transformers and generators
- Overcurrent and short-circuit protection of various devices connected to the power system, for example shunt capacitor banks, shunt reactors and motors
- General backup protection

51P/50P is used for single-phase, two-phase and three-phase non-directional overcurrent and short-circuit protection. Typically, overcurrent protection is used for clearing two and three-phase short circuits. Therefore, the user can choose how many phases, at minimum, must have currents above the pickup level for the function to trip. When the number of pickup-phase settings is set to “1 out of 3”, the operation of 51P/50P is enabled with the presence of high current in one-phase.

When the setting is “2 out of 3” or “3 out of 3”, single-phase faults are not detected. The setting “3 out of 3” requires the fault to be present in all three phases.

Many applications require several steps using different current pickup levels and time delays. 51P/50P consists of three protection stages:

- Low 51P
- High 50P-1/2
- Instantaneous 50P-3.

51P is used for overcurrent protection. The function contains several types of time-delay characteristics. 50P-1/2 and 50P-3 are used for fast clearance of very high overcurrent situations.

**Transformer and busbar overcurrent protection with reverse blocking principle**

By implementing a full set of overcurrent protection stages and blocking channels between the protection stages of the incoming feeders, bus-tie and outgoing feeders, it is possible to speed up the operation of overcurrent protection in the busbar and transformer LV-side faults without impairing the selectivity. Also, the security degree of busbar protection is increased, because there is now a dedicated, selective and fast busbar protection functionality which is based on the blockable overcurrent protection principle. The additional time selective stages on the transformer HV and LV-sides provide increased security of backup protection for the transformer, busbar and also for the outgoing feeders.

Depending on the overcurrent stage in question, the selectivity of the scheme in Figure 11 is based on the operating current, operating time or blockings between successive overcurrent stages. With blocking channels, the operating time of the protection can be drastically shortened if compared to the simple time selective protection. In addition to the busbar protection, this blocking principle is applicable for the protection of transformer LV terminals and short lines. The functionality and performance of the proposed overcurrent protections can be summarized as seen in the table.
Table 105: Proposed functionality of numerical transformer and busbar overcurrent protection. DT = definite time, IDMT = inverse definite minimum time

</table>

In case the bus-tie breaker is open, the operating time of the blockable overcurrent protection is approximately 100 ms (relaying time). When the bus-tie breaker is closed, that is, the fault current flows to the faulted section of the busbar from two directions, the operation time becomes as follows: first the bus-tie relay unit trips the tie breaker in the above 100 ms, which reduces the fault current to a half. After this the incoming feeder relay unit of the faulted bus section trips the breaker in approximately 250 ms (relaying time), which becomes the total fault clearing time in this case.

![Figure 37: Numerical overcurrent protection functionality for a typical sub-transmission/distribution substation (feeder protection not shown). Blocking output = digital output signal from the start of a protection stage, Blocking in = digital input signal to block the operation of a protection stage.](image)

The operating times of the time selective stages are very short, because the grading margins between successive protection stages can be kept short. This is mainly due to the advanced measuring principle allowing a certain degree of CT saturation, good operating accuracy and short retardation times of the numerical units. So, for example, a grading
margin of 150 ms in the DT mode of operation can be used, provided that the circuit breaker interrupting time is shorter than 60 ms.

The sensitivity and speed of the current-selective stages become as good as possible due to the fact that the transient overreach is practically zero. Also, the effects of switching inrush currents on the setting values can be reduced by using the relay logic, which recognizes the transformer energizing inrush current and blocks the operation or multiplies the current pickup value setting of the selected overcurrent stage with a predefined multiplier setting.

Finally, a dependable trip of the overcurrent protection is secured by both a proper selection of the settings and an adequate ability of the measuring transformers to reproduce the fault current. This is important in order to maintain selectivity and also for the protection to operate without additional time delays. For additional information about available measuring modes and current transformer requirements, see the General function block features section in this manual.

**Radial outgoing feeder overcurrent protection**

The basic requirements for feeder overcurrent protection are adequate sensitivity and operation speed taking into account the minimum and maximum fault current levels along the protected line, selectivity requirements, inrush currents and the thermal and mechanical withstand of the lines to be protected.

In many cases the above requirements can be best fulfilled by using multiple-stage overcurrent units. Figure 12 shows an example of this. A brief coordination study has been carried out between the incoming and outgoing feeders.

The protection scheme is implemented with three-stage numerical overcurrent protection where the low-set stage 51P operates in IDMT-mode and the two higher stages 50P-1/2 and 50P-3 in DT-mode. Also the thermal withstand of the line types along the feeder and maximum expected inrush currents of the feeders are shown. Faults occurring near the station, where the fault current levels are the highest, are cleared rapidly by the instantaneous stage in order to minimize the effects of severe short circuit faults. The influence of the inrush current is taken into consideration by connecting the inrush current detector to the pickup value multiplying input of the instantaneous stage. In this way, the pickup value is multiplied with a predefined setting during the inrush situation and nuisance tripping can be avoided.
The coordination plan is an effective tool to study the operation of time selective operation characteristics. All the points mentioned earlier, required to define the overcurrent protection parameters, can be expressed simultaneously in a coordination plan. In Figure 13, the coordination plan shows an example of operation characteristics in the LV-side incoming feeder and radial outgoing feeder.

4.1.2.2 Function block

**Figure 40:** Function block

4.1.2.3 Functionality

The three-phase overcurrent protection 67/51P and 67/50P is used as one-phase, two-phase or three-phase directional overcurrent and short-circuit protection for feeders.

67/51P and 67/50P picks up when the value of the current exceeds the set limit and directional criterion is fulfilled. The trip time characteristics for low stage 67/51P and
67/50P-1 and high stage 67/50P-2 can be selected to be either definite time (DT) or inverse definite minimum time (IDMT).

In the DT mode, the function trips after a predefined trip time and resets when the fault current disappears. The IDMT mode provides current-dependent timer characteristics.

The function contains a blocking functionality. It is possible to block function outputs, timers or the function itself, if desired.

### 4.1.2.4 Operation principle

The function can be enabled and disabled with the Operation setting. The corresponding parameter values are “Enable” and “Disable.”

The single-phase directional overcurrent protection function is used as one-phase and three-phase overcurrent and short circuit protection. The phase-tripping mode is selected with the Configuration setting Recloser type.

The operation in either tripping mode can be described by using a module diagram (see Figure 41). Some modules have different functionality depending on whether the function is in one-phase or three-phase tripping mode. All the blocks in the diagram are explained in the next sections.

**Figure 41: Functional module diagram**

**Directional calculation**

The directional calculation compares the current phasors to the polarizing phasor. The user can select the suitable one from different polarization quantities which are the positive sequence voltage, negative sequence voltage, self polarizing (faulted) voltage and cross...
polarizing voltages (healthy voltages). The polarizing method is defined with the *Pol quantity* setting.

<table>

<tr>
<td>Cross pol</td>
<td>Cross polarization</td>
</tr>
</tbody>
</table>

The directional operation can be selected with the *Directional mode* setting. The user can select either “Non-directional”, “Forward” or “Reverse” operation. By setting the value of *Allow Non Dir* to “True”, the non-directional operation is allowed when the directional information is invalid.

The *Characteristic angle* setting is used to turn the directional characteristic. The value of *Characteristic angle* should be chosen in such a way that all the faults in the operating direction are seen in the operating zone and all the faults in the opposite direction are seen in the non-operating zone. The value of *Characteristic angle* depends on the network configuration.

Reliable operation requires both the operating and polarizing quantities to exceed certain minimum amplitude levels. The minimum amplitude level for the operating quantity (current) is set with the *Min Trip Current* setting. The minimum amplitude level for the polarizing quantity (voltage) is set with the *Min operate voltage* setting. If the amplitude level of the operating quantity or polarizing quantity is below the set level, the direction information of the corresponding phase is set to “Unknown”.

The polarizing quantity validity can remain valid even if the amplitude of the polarizing quantity falls below the value of the *Min operate voltage* setting. In this case, the directional information is provided by a special memory function for a time defined with the *Voltage Mem time* setting.

DPHxPDO is provided with a memory function to secure a reliable and correct directional relay operation in case of a close short circuit or an earth fault characterized by an extremely low voltage. At sudden loss of the polarization quantity, the angle difference is calculated on the basis of a fictive voltage. The fictive voltage is calculated using the positive phase sequence voltage measured before the fault occurred, assuming that the voltage is not affected by the fault. The memory function enables the function to operate up to a maximum of three seconds after a total loss of voltage. This time can be set with the *Voltage Mem time* setting. The voltage memory cannot be used for the “Negative sequence voltage” polarization because it is not possible to substitute the positive sequence voltage for negative sequence voltage without knowing the network unsymmetry level. This is the reason why the fictive voltage angle and corresponding direction information are frozen immediately for this polarization mode when the need for voltage memory arises and these are kept frozen until the time set with *Voltage Mem time* elapses.

When the voltage falls below *Min operate voltage* at a close fault, the fictive voltage is used to determine the phase angle. The measured voltage is applied again as soon as the voltage rises above *Min operate voltage* and hysteresis. The fictive voltage is also discarded if the measured voltage stays below *Min Trip Voltage* and hysteresis for longer
than *Voltage Mem time* or if the fault current disappears while the fictive voltage is in use. When the voltage is below *Min Trip Voltage* and hysteresis and the fictive voltage is unusable, the fault direction cannot be determined. The fictive voltage can be unusable for two reasons:

- The fictive voltage is discarded after *Voltage Mem time*
- The phase angle cannot be reliably measured before the fault situation.

![Figure 42: Operating zones at minimum magnitude levels](image)

**Level detector**

The measured phase currents are compared phase-wise with the set *Pickup value* and, if enabled, the *Pickup block value*. If the measured value exceeds the set *Pickup value*, and is less than the *Pickup block value*, the level detector reports the pickup to the phase selection logic. If the ENA MULT input is active, the *Pickup value* setting is multiplied by the *Pickup value Mult* setting.

Do not set the multiplier setting *Pickup value Mult* higher than necessary. If the value is too high, the function may not trip at all during an inrush followed by a fault, no matter how severe the fault is.
The relay does not accept the Pickup value or Pickup value Mult setting if the product of these settings exceeds the Pickup value setting range.

The *Pickup block value* is not affected by the ENA_MULT input or the *Pickup value Mult* setting.

The pickup value multiplication is normally done when the inrush detection function (INR) is connected to the ENA_MULT input.

![Figure 43: Pickup value behavior with ENA_MULT input activated](image)

**Phases selection logic**

This logic is only active in three-phase tripping mode. If the fault criteria are fulfilled in the level detector, the phase selection logic detects the phase or phases in which the measured current exceeds the setting. If the phase information matches the *Num of pickup phases* setting, the phase selection logic activates the timer module.

When in single-phase tripping mode, the *Num of pickup phases* setting has no affect on operation and the outputs of the level detector are passed directly to the corresponding timer module.

**Timer**

Once activated, the timer activates the PICKUP output. Depending on the value of the *Operating curve type* setting, the time characteristics are according to DT or IDMT. When
the operation timer has reached the value of *Trip delay time* in the DT mode or the maximum value defined by the inverse time curve and the *Time added* time has expired, the TRIP output is activated.

When the user programmable IDMT curve is selected, the operate time characteristics are defined by the parameters *Curve parameter A*, *Curve parameter B*, *Curve parameter C*, *Curve parameter D* and *Curve parameter E*.

If a drop-off situation happens, that is, a fault suddenly disappears before the trip delay is exceeded, the timer reset state is activated. The functionality of the timer in the reset state depends on the combination of the *Operating curve type*, *Type of reset curve* and *Reset delay time* settings. When the DT characteristic is selected, the reset timer runs until the set *Reset delay time* value is exceeded. When the IDMT curves are selected, the *Type of reset curve* setting can be set to “Immediate”, “Def time reset” or “Inverse reset”. The reset curve type “Immediate” causes an immediate reset. With the reset curve type “Def time reset”, the reset time depends on the *Reset delay time* setting. With the reset curve type “Inverse reset”, the reset time depends on the current during the drop-off situation. If the drop-off situation continues, the reset timer is reset and the PICKUP output is deactivated.

The “Inverse reset” selection is only supported with ANSI or user programmable types of the IDMT operating curves. If another operating curve type is selected, an immediate reset occurs during the drop-off situation.

The setting *Time multiplier* is used for scaling the IDMT trip and reset times.

The setting parameter *Minimum trip time* defines the minimum desired trip time for IDMT. The setting is applicable only when the IDMT curves are used.

The *Minimum trip time* setting should be used with great care because the operation time is according to the IDMT curve, but always at least the value of the *Minimum operate time* setting. For more information, see the General function block features section in this manual.

The timer calculates the pickup duration (PICKUP_DUR) value which indicates the percentage ratio of the pickup situation and the set trip time. The value is available through the Monitored data view.

**Blocking logic**

There are three operation modes in the blocking functionality. The operation modes are controlled by the BLOCK input and the global setting “*Configuration/System/Blocking mode*” which selects the blocking mode. The BLOCK input can be controlled by a binary input, a horizontal communication input or an internal signal of the relay program. The influence of the BLOCK signal activation is preselected with the global setting *Blocking mode*.

The *Blocking mode* setting has three blocking methods. In the “Freeze timers” mode, the trip timer is frozen to the prevailing value. In the “Block all” mode, the whole function is...
The function operates on three alternative measurement modes: “RMS”, “DFT” and “Peak-to-Peak”. The measurement mode is selected with the Measurement mode setting.

</table>

The sector limits are always given as positive degree values.

In the forward operation area, the Max forward angle setting gives the counterclockwise sector and the Min forward angle setting gives the corresponding clockwise sector, measured from the Characteristic angle setting.

In the backward operation area, the Max reverse angle setting gives the counterclockwise sector and the Min reverse angle setting gives the corresponding clockwise sector, a measurement from the Characteristic angle setting that has been rotated 180 degrees.

 Relay characteristic angle (RCA) is set positive if the operating current lags the polarizing quantity and negative if the operating current leads the polarizing quantity.
Criterion for per phase direction information | The value for DIR_A/_B/_C
---|---
The ANGLE_X is not in any of the defined sectors, or the direction cannot be defined due to low amplitude | 0 = unknown
The ANGLE_X is in the forward sector | 1 = forward
The ANGLE_X is in the reverse sector | 2 = backward
(The ANGLE_X is in both forward and reverse sectors, that is, when the sectors are overlapping) | 3 = both

Criterion for phase combined direction information | The value for DIRECTION
---|---
The direction information (DIR_X) for all phases is unknown | 0 = unknown
The direction information (DIR_X) for at least one phase is forward, none being in reverse | 1 = forward
The direction information (DIR_X) for at least one phase is reverse, none being in forward | 2 = backward
The direction information (DIR_X) for some phase is forward and for some phase is reverse | 3 = both

FAULT_DIR gives the detected direction of the fault during fault situations, that is, when the PICKUP output is active.

</tr>
</tbody>
</table>

The polarizing quantity is rotated with 90 degrees. The characteristic angle is assumed to be $\sim 0$ degrees.
Figure 47: Single-phase ground fault, phase A

In an example of the phasors in a two-phase short-circuit failure where the fault is between the phases B and C, the angle difference is measured between the polarizing quantity $V_{AB}$ and operating quantity $I_B - I_C$ marked as $\phi$. 
When the negative voltage is used as the polarizing quantity, the angle difference between the operating and polarizing quantity is calculated with the same formula for all fault types:

$$\text{ANGLE } X = \varphi(-\sqrt{2}) - \varphi(I_2) - \varphi_{RCA}$$  \hspace{1cm} (Equation 1)

This means that the actuating polarizing quantity is $-\sqrt{2}$. 

**Negative-sequence voltage as polarizing quantity**

The equations are valid when network rotating direction is counterclockwise, that is, ABC. If the network rotating direction is reversed, 180 degrees is added to the calculated angle difference. This is done automatically with a system parameter *Phase rotation*.

</tbody>
</table>
Network rotating direction

Typically, the network rotating direction is counterclockwise and defined as “ABC”. If the network rotating direction is reversed, meaning clockwise, that is, “ACB”, the equations for calculating the angle difference need to be changed. The network rotating direction is defined with a system parameter Phase rotation. The change in the network rotating direction affects the phase-to-phase voltages polarization method where the calculated angle difference needs to be rotated 180 degrees. Also, when the sequence components are used, which are the positive-sequence voltage or negative-sequence voltage components, the calculation of the components is affected but the angle difference calculation remains the same. When the phase-to-ground voltages are used as the polarizing method, the network rotating direction change has no effect on the direction calculation.

The network rotating direction is set in the relay using the parameter in the HMI menu: Configuration > System > Phase rotation. The default parameter value is “ABC”.

![Figure 50: Phasors in a single-phase ground fault, phase A to ground, and a two-phase short circuit, phases B-C, are short-circuited when the polarizing quantity is the positive-sequence voltage V1](image-url)
4.1.2.7 Application

67/51P and 67/50P is used as short-circuit protection in three-phase distribution or subtransmission networks operating at 50 or 60 Hz.

In radial networks, phase overcurrent relays are often sufficient for the short circuit protection of lines, transformers and other equipment. The current-time characteristic should be chosen according to the common practice in the network. It is recommended to use the same current-time characteristic for all overcurrent relays in the network. This includes the overcurrent protection of transformers and other equipment.

The phase overcurrent protection can also be used in closed ring systems as short circuit protection. Because the setting of a phase overcurrent protection system in closed ring networks can be complicated, a large number of fault current calculations are needed. There are situations with no possibility to have the selectivity with a protection system based on overcurrent relays in a closed ring system.

In some applications, the possibility of obtaining the selectivity can be improved significantly if 67/51P and 67/50P is used. This can also be done in the closed ring networks and radial networks with the generation connected to the remote in the system thus giving fault current infeed in reverse direction. Directional overcurrent relays are also used to have a selective protection scheme, for example in case of parallel distribution lines or power transformers fed by the same single source. In ring connected supply feeders between substations or feeders with two feeding sources, 67/51P and 67/50P is also used.

Parallel lines or transformers

When the lines are connected in parallel and if a fault occurs in one of the lines, it is practical to have 67/51P and 67/50P to detect the direction of the fault. Otherwise, there is a risk that the fault situation in one part of the feeding system can de-energize the whole system connected to the LV side.
67/51P and 67/50P can be used for parallel operating transformer applications. In these applications, there is a possibility that the fault current can also be fed from the LV-side up to the HV-side. Therefore, the transformer is also equipped with directional overcurrent protection.

**Closed ring network topology**

The closed ring network topology is used in applications where electricity distribution for the consumers is secured during network fault situations. The power is fed at least from two directions which means that the current direction can be varied. The time grading between the network level stages is challenging without unnecessary delays in the time settings. In this case, it is practical to use the directional overcurrent relays to achieve a selective protection scheme. Directional overcurrent functions can be used in closed ring applications. The arrows define the operating direction of the directional functionality. The double arrows define the non-directional functionality where faults can be detected in both directions.

4.1.3.2 Function block

4.1.3.3 Functionality

The ground-fault function 51N/50N or 51G/50G is used as non-directional ground-fault protection for feeders.

The function picks up and trips when the measured (IG) or calculated (IN) ground current exceeds the set limit. The trip time characteristic for low stage 51N/G and high stage 50N/G-1/2 can be selected to be either definite time (DT) or inverse definite minimum time (IDMT). The instantaneous stage 50N/G-3 always trips with the DT characteristic.

In the DT mode, the function trips after a predefined trip time and resets when the fault current disappears. The IDMT mode provides current-dependent timer characteristics.

The function contains a blocking functionality. It is possible to block function outputs, timers or the function itself, if desired.

4.1.3.4 Operation principle

The function can be enabled and disabled with the Operation setting. The corresponding parameter values are Enable and Disable.

The operation of non-directional ground-fault protection can be described by using a module diagram. All the blocks in the diagram are explained in the next sections.

Figure 56: Functional module diagram. \( I_0 \) represents the residual current.

Level detector

The measured ground current is compared with the set Pickup value and, if enabled, the Pickup block value. If the measured value exceeds the set Pickup value, and is less than the Pickup block value, the level detector sends an enable-signal to the timer module. If the ENA_MULT input is active, the Pickup value setting is multiplied by the Pickup value Mult setting.
Do not set the multiplier setting *Pickup value Mult* higher than necessary. If the value is too high, the function may not trip at all during an inrush current followed by a non-directional ground fault current, no matter how severe the fault is.

The relay does not accept the Pickup value or Pickup value Mult setting if the product of these settings exceeds the Pickup value setting range.

The pickup value multiplication is normally done when the inrush detection function (INR) is connected to the *ENA_MULT* input.

**Timer**

Once activated, the timer activates the PICKUP output. Depending on the value of the *Operating curve type* setting, the time characteristics are according to DT or IDMT. When the operation timer has reached the value of *Trip delay time* in the DT mode or the maximum value defined by the inverse time curve and the *Time added* time has expired, the TRIP output is activated.

When the user programmable IDMT curve is selected, the operate time characteristics are defined by the parameters *Curve parameter A*, *Curve parameter B*, *Curve parameter C*, *Curve parameter D* and *Curve parameter E*.

If a drop-off situation happens, that is, a fault suddenly disappears before the trip delay is exceeded, the timer reset state is activated. The functionality of the timer in the reset state depends on the combination of the *Operating curve type*, *Type of reset curve* and *Reset delay time* settings. When the DT characteristic is selected, the reset timer runs until the set *Reset delay time* value is exceeded. When the IDMT curves are selected, the *Type of reset curve* setting can be set to “Immediate”, “Def time reset” or “Inverse reset”. The reset curve type “Immediate” causes an immediate reset. With the reset curve type “Def time reset”, the reset time depends on the *Reset delay time* setting. With the reset curve type “Inverse reset”, the reset time depends on the current during the drop-off situation. If the drop-off situation continues, the reset timer is reset and the PICKUP output is deactivated.

The “Inverse reset” selection is only supported with ANSI or user programmable types of the IDMT operating curves. If another operating curve type is selected, an immediate reset occurs during the drop-off situation.

The setting *Time multiplier* is used for scaling the IDMT trip and reset times.

The setting parameter *Minimum trip time* defines the minimum desired trip time for IDMT. The setting is applicable only when the IDMT curves are used.
The timer calculates the pickup duration (PICKUP_DUR) value which indicates the percentual ratio of the pickup situation and the set trip time. The value is available through the Monitored data view.

**Blocking logic**

There are three operation modes in the blocking functionality. The operation modes are controlled by the BLOCK input and the global setting “Configuration/System/Blocking mode” which selects the blocking mode. The BLOCK input can be controlled by a binary input, a horizontal communication input or an internal signal of the relay program. The influence of the BLOCK signal activation is preselected with the global setting Blocking mode.

The Blocking mode setting has three blocking methods. In the “Freeze timers” mode, the trip timer is frozen to the prevailing value. In the “Block all” mode, the whole function is blocked and the timers are reset. The “Block TRIP output” mode, the function operates normally but the TRIP output is not activated.

**4.1.3.5 Measurement modes**

The function operates on three alternative measurement modes: “RMS”, “DFT” and “Peak-to-Peak”. The measurement mode is selected with the Measurement mode setting.

<table>
<thead>
<tr>
<th>Measurement mode</th>
<th>Supported measurement modes</th>

<td>51N/G</td>
</tr>
<tr>
<td>DFT</td>
<td>51N/G</td>
</tr>
<tr>
<td>Peak-to-Peak</td>
<td>51N/G</td>
</tr>
</tbody>
</table>

For a detailed description of the measurement modes, see the General function block features section in this manual.

**4.1.3.6 Timer characteristics**

51N/50N or 51G/50G supports both DT and IDMT characteristics. The user can select the timer characteristics with the Operating curve type and Type of reset curve settings. When the DT characteristic is selected, it is only affected by the Trip delay time and Reset delay time settings.

The relay provides 16 IDMT characteristics curves, of which seven comply with the IEEE C37.112 and six with the IEC 60255-3 standard. Two curves follow the special characteristics of ABB praxis and are referred to as RI and RD. In addition to this, a user programmable curve can be used if none of the standard curves are applicable. The user...
can choose the DT characteristic by selecting the *Operating curve type* values “ANSI Def. Time” or “IEC Def. Time”. The functionality is identical in both cases.

The following characteristics, which comply with the list in the IEC 61850-7-4 specification, indicate the characteristics supported by different stages:

Section 4
Protection functions

### 4.1.3.7 Application

51N/50N or 51G/50G is designed for protection and clearance of ground faults in distribution and sub-transmission networks where the neutral point is non-grounded.

---

**Table 145: Reset time characteristics supported by different stages**

<table>
<thead>
<tr>
<th>Reset curve type</th>
<th>Supported by</th>
<th>51N/G</th>
<th>50N/G-1/2</th>

<td>Available for all reset time curves</td>
<td></td>
</tr>
<tr>
<td>Inverse reset</td>
<td>x</td>
<td>x</td>
<td>Available only for ANSI and user programmable curves</td>
<td></td>
</tr>
</tbody>
</table>

The *Type of reset curve* setting does not apply to 50N/G-3 or when the DT operation is selected. The reset is purely defined by the *Reset delay time* setting.

50N/G-3 supports only definite time characteristics.

For a detailed description of timers, see the General function block features section in this manual.
(isolated) or grounded via a resonance coil or through low resistance. It also applies to solidly grounded networks and ground-fault protection of different equipment connected to the power systems, such as shunt capacitor bank or shunt reactors and for backup ground-fault protection of power transformers.

Many applications require several steps using different current pickup levels and time delays. 51N/50N or 51G/50G consists of three different protection stages:

- Low 51N/G
- High 50N/G-1/2
- Instantaneous 50N/G-3.

51N/G contains several types of time-delay characteristics. 50N/G-1/2 and 50N/G-3 are used for fast clearance of serious ground faults.

</tr>
</tbody>
</table>
4.1.4.2 Function block

4.1.4.3 Functionality

The ground-fault function 67/51N and 67/50N is used as directional ground-fault protection for feeders.

There are three different polarization signals - measured zero sequence voltage, calculated zero sequence voltage and negative sequence voltage. The function picks up and trips when the zero sequence current ($I_0$) and zero sequence voltage ($-V_0$) exceed the set limits and the angle between them is inside the set operating sector. The function also picks up and trips when the negative sequence current ($I_2$) and negative sequence voltage ($-V_2$) exceed the set limits and the angle between them is inside the set operating sector. The trip time characteristic for low stage (67/51N and 67/50N-1) and high stage (67/50N-2) can be selected to be either definite time (DT) or inverse definite minimum time (IDMT).

In the DT mode, the function trips after a predefined trip time and resets when the fault current disappears. The IDMT mode provides current-dependent timer characteristics.

The function contains a blocking functionality. It is possible to block function outputs, timers or the function itself, if desired.

4.1.4.4 Operation principle

The function can be enabled and disabled with the Operation setting. The corresponding parameter values are Enable and Disable.

The operation of directional earth-fault protection can be described by using a module diagram. All the modules in the diagram are explained in the next sections.
Figure 58: Functional module diagram. $I_0$ and $V_0$ represent the zero sequence current and zero sequence voltage.

**Level detector**

The measured ground current is compared with the set *Pickup value*. For directional operation, the residual voltage (-$U_o$) also needs to be compared with the set *Voltage pickup value*. If both limits are exceeded, the level detector sends an enable-signal to the timer module. When the *Enable voltage limit* setting is set to “False”, the *Voltage pickup value* has no effect and the level detection is purely based on the ground current. If the *ENA_MULT* input is active, the *Pickup value* setting is multiplied by the *Pickup value Mult* setting.

Do not set the multiplier setting *Pickup value Mult* higher than necessary. If the value is too high, the function may not trip at all during an inrush current followed by a directional earth-fault current, no matter how severe the fault is.

The relay does not accept the Pickup value or Pickup value Mult setting if the product of these settings exceeds the Pickup value setting range.

The pickup value multiplication is normally done when the inrush detection function (INR) is connected to the *ENA_MULT* input.

**Directional calculation**

The directional calculation module monitors the angle between the operating current and polarizing voltage. When the angle is in the operation sector, the module sends the enable signal to the timer module.
For defining the operation sector, there are five modes available through the *Operation mode* setting.

### Table 162: Operation modes

<table>
<thead>
<tr>
<th>Operation mode</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Phase angle</td>
<td>The operating sectors for forward and reverse are defined with the settings Min forward angle, Max forward angle, Min reverse angle and Max reverse angle.</td>
</tr>
<tr>
<td>IoSin</td>
<td>The operating sectors are defined as “forward” when the mathematical expression has a positive value and “reverse” when the value is negative.</td>
</tr>
<tr>
<td>IoCos</td>
<td>As “IoSin” mode. Only cosine is used for calculating the operation current.</td>
</tr>
<tr>
<td>Phase angle 80</td>
<td>The sector maximum values are frozen to 80 degrees, respectively. Only Min forward angle and Min reverse angle are settable.</td>
</tr>
<tr>
<td>Phase angle 88</td>
<td>The sector maximum values are frozen to 88 degrees. Otherwise as “Phase angle 80” mode.</td>
</tr>
</tbody>
</table>

The directional operation can be selected with the *Directional mode* setting. The user can select either “Non-directional”, “Forward” or “Reverse” operation. The operation criterion is selected with the *Operation mode* setting. By setting *Allow Non Dir* to “True”, non-directional operation is allowed when directional information is invalid.

The *Characteristic angle* setting is used in “Phase angle” mode to adjust the operation according to the method of neutral point earthing so that in an isolated network the *Characteristic angle* ($\phi_{RCA}$) = -90° and in a compensated network $\phi_{RCA}$ = 0°. In addition, the characteristic angle can be changed via the control signal RCA_CTL, in which case the alternatives are -90° and 0°. The operation of RCA_CTL depends on the *Characteristic angle* setting.

The *Correction angle* setting can be used to improve selectivity when there are inaccuracies due to measurement transformers. The setting decreases the operation sector. The correction can only be used with the “IoCos” or “IoSin” modes.

The minimum signal level which allows directional operation can be set by using the *Min trip current* and *Min trip voltage* settings.

When polarizing quantity (residual voltage (-Uo)) is inverted because of switched voltage measurement cables, the correction can be done by setting the *Pol reversal* to “True” which turns polarizing quantity by 180 degrees.

For definitions of different directional earth-fault characteristics, see the Directional earth-fault characteristics section in this manual.

The directional calculation module calculates several values which are presented in the monitored data.
Table 163: Monitored data values

<table>
<thead>
<tr>
<th>Monitored data values</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>FAULT_DIR</td>
<td>The detected direction of fault during fault situations, that is, when START output is active.</td>
</tr>
<tr>
<td>DIRECTION</td>
<td>The momentary operating direction indication output.</td>
</tr>
<tr>
<td>ANGLE</td>
<td>Also called operating angle, shows the angle difference between the VG (polarizing quantity) and Io (operating quantity).</td>
</tr>
<tr>
<td>ANGLE_RCA</td>
<td>The angle difference between the operating angle and Characteristic angle, that is, ANGLE_RCA = ANGLE – Characteristic angle.</td>
</tr>
<tr>
<td>I_OPER</td>
<td>The current that is used for fault detection. If the Operation mode setting is ‘Phase angle’, ‘Phase angle 80’ or ‘Phase angle 88’, I_OPER is the measured or calculated residual current. If the Operation mode setting is ‘IoSin’, I_OPER is calculated as follows I_OPER = Io x sin(ANGLE). If the Operation mode setting is “IoCos”, I_OPER is calculated as follows I_OPER = Io x cos(ANGLE).</td>
</tr>
</tbody>
</table>

Monitored data values are accessible on the LHMI or through tools via communications.

Timer

Once activated, the timer activates the PICKUP output. Depending on the value of the Operating curve type setting, the time characteristics are according to DT or IDMT. When the operation timer has reached the value of Trip delay time in the DT mode or the maximum value defined by the inverse time curve and the Time adder time has expired, the TRIP output is activated.

When the user programmable IDMT curve is selected, the operate time characteristics are defined by the parameters Curve parameter A, Curve parameter B, Curve parameter C, Curve parameter D and Curve parameter E.

If a drop-off situation happens, that is, a fault suddenly disappears before the trip delay is exceeded, the timer reset state is activated. The functionality of the timer in the reset state depends on the combination of the Operating curve type, Type of reset curve and Reset delay time settings. When the DT characteristic is selected, the reset timer runs until the set Reset delay time value is exceeded. When the IDMT curves are selected, the Type of reset curve setting can be set to “Immediate”, “Def time reset” or “Inverse reset”. The reset curve type “Immediate” causes an immediate reset. With the reset curve type “Def time reset”, the reset time depends on the Reset delay time setting. With the reset curve type “Inverse reset”, the reset time depends on the current during the drop-off situation. If the drop-off situation continues, the reset timer is reset and the PICKUP output is deactivated.

The “Inverse reset” selection is only supported with ANSI or user programmable curves. If another operating curve type is selected, an immediate reset occurs during the drop-off situation.

The setting Time multiplier is used for scaling the IDMT trip and reset times.
The setting parameter *Minimum trip time* defines the minimum desired trip time for IDMT. The setting is applicable only when the IDMT curves are used.

The *Minimum trip time* setting should be used with great care because the operation time is according to the IDMT curve, but always at least the value of the *Minimum operate time* setting. For more information, see the General function block features section in this manual.

The timer calculates the pickup duration (PICKUP_DUR) value which indicates the percentage ratio of the pickup situation and the set trip time. The value is available through the Monitored data view.

**Blocking logic**

There are three operation modes in the blocking functionality. The operation modes are controlled by the BLOCK input and the global setting “Configuration/System/Blocking mode” which selects the blocking mode. The BLOCK input can be controlled by a binary input, a horizontal communication input or an internal signal of the relay program. The influence of the BLOCK signal activation is preselected with the global setting *Blocking mode*.

The *Blocking mode* setting has three blocking methods. In the “Freeze timers” mode, the trip timer is frozen to the prevailing value. In the “Block all” mode, the whole function is blocked and the timers are reset. In the “Block TRIP output” mode, the function operates normally but the TRIP output is not activated.

**Directional ground-fault principles**

In many cases it is difficult to achieve selective ground-fault protection based on the magnitude of zero sequence current only. To obtain a selective ground-fault protection scheme, it is necessary to take the phase angle of $I_0$ into account. This is done by comparing the phase angle of $I_0$ to that of the zero sequence voltage ($-V_0$).

**Relay characteristic angle**

The *Characteristic angle*, also known as Relay Characteristic Angle (RCA), Relay Base Angle or Maximum Torque Angle (MTA), is used in the “Phase angle” mode to turn the directional characteristic, if the expected fault current angle does not coincide with the polarizing quantity to produce the maximum torque. That is, RCA is the angle between the maximum torque line and polarizing quantity. If the polarizing quantity is in phase with the maximum torque line, RCA is 0 degrees. The angle is positive if operating current lags the polarizing quantity and negative if it leads the polarizing quantity.

**Example 1.**

The “Phase angle” mode is selected, compensated network ($\varphi_{RCA} = 0$ deg)

$\Rightarrow$ *Characteristic angle* = 0 deg
Example 2.

The “Phase angle” mode is selected, solidly grounded network ($\phi_{RCA} = +60$ deg)

$=>$ Characteristics angle = $+60$ deg
Section 4
Protection functions

Figure 60: Definition of the relay characteristic angle, RCA=+60 degrees in a solidly grounded network

Example 3.

The “Phase angle” mode is selected, isolated network (ϕRCA = -90 deg)

⇒ Characteristic angle = -90 deg
Directional ground-fault protection in an isolated neutral network

In isolated networks, there is no intentional connection between the system neutral point and ground. The only connection is through the line-to-ground capacitances ($C_0$) of phases and leakage resistances ($R_0$). This means that the zero sequence current is mainly capacitive and has a phase shift of $-90$ degrees compared to the residual voltage ($-V_0$). Consequently, the relay characteristic angle ($RCA$) should be set to $-90$ degrees and the operation criteria to $I_0\sin(\phi)$ or phase angle. The width of the operating sector in the phase angle criteria can be selected with the settings Min forward angle, Max forward angle, Min reverse angle or Max reverse angle. The figure below describes how ground fault current is defined in isolated neutral networks.

For definitions of different directional ground-fault characteristics, see Directional ground-fault principles.
Directional ground-fault protection in a compensated network

In compensated networks, the capacitive fault current and the inductive resonance coil current compensate each other. The protection cannot be based on the reactive current measurement, since the current of the compensation coil would disturb the operation of the relays. In this case, the selectivity is based on the measurement of the active current component. The magnitude of this component is often small and must be increased by means of a parallel resistor in the compensation equipment. When measuring the resistive part of the zero sequence current, the relay characteristic angle (RCA) should be set to 0 degrees and the operation criteria to \( I_0 \cos(\varphi) \) or phase angle. The figure below describes how ground fault current is defined in compensated neutral networks.
The Petersen coil or the grounding resistor may be temporarily out of operation. To keep the protection scheme selective, it is necessary to update the characteristic angle setting accordingly. This is done with an auxiliary input in the relay which receives a signal from an auxiliary switch of the disconnector of the Petersen coil in compensated networks or of the grounding resistor in grounded networks. As a result the characteristic angle is set automatically to suit the grounding method used. The RCA_CTL input can be used to change the $I_0$ characteristic:

**Table 164: Relay characteristic angle control in $I_0\sin(\phi)$ and $I_0\cos(\phi)$ operation criteria**

**Usage of the extended phase angle characteristic**

In addition to the RCA_CTL input, the extended phase angle characteristic can be used when the compensation coil is temporarily disconnected in compensated networks. When the extended operation area is used, the operation area is wide enough to detect ground faults selectively in compensated networks regardless of whether the compensation coil is connected or not. Therefore, the RCA_CTL input is not required if the extended operation area is used.

Sometimes the distance between the start point and the relay is long which makes it impractical to apply the scheme based on signal wiring between the relay and the Petersen coil.
coil or the grounding resistor. This is the case for instance, when a directional ground-fault relay is used in an MV-switching substation some kilometers from the HV/MV-substation in which the grounding facilities are located. Another example is when HV/MV-substations are connected in parallel but located far from each other.

It is easy to give the tripping sector such a width that all possible directions of the $I_0$-phasors of a faulty line are covered by one and the same sector. Thus, the problem of setting the characteristic angle according to the grounding status of the network is easily solved. There is no need to change any settings when a Petersen coil or a grounding resistor is switched on or off. Auxiliary switches and other pieces of extra hardware are no longer required for ensuring the selectivity of the directional ground-fault protection.

Figure 64: Extended operation area in directional ground-fault protection

### 4.1.4.6 Measurement modes

The function operates on three alternative measurement modes: "RMS", "DFT" and "Peak-to-Peak". The measurement mode is selected with the Measurement mode setting.

<table>

For a detailed description of the measurement modes, see the General function block features section in this manual.
4.1.4.7 Timer characteristics

67/51N and 67/50N supports both DT and IDMT characteristics. The user can select the timer characteristics with the *Operating curve type* setting.

The relay provides 16 IDMT characteristics curves, of which seven comply with the IEEE C37.112 and six with the IEC 60255-3 standard. Two curves follow the special characteristics of ABB praxis and are referred to as RI and RD. In addition to this, a user programmable curve can be used if none of the standard curves are applicable. The user can choose the DT characteristic by selecting the *Operating curve type* values “ANSI Def. Time” or “IEC Def. Time”. The functionality is identical in both cases.

The following characteristics, which comply with the list in the IEC 61850-7-4 specification, indicate the characteristics supported by different stages:

### 4.1.4.8 Directional ground-fault characteristics

#### Phase angle characteristic

The operation criterion phase angle is selected with the *Operation mode* setting using the value “Phase angle”.

When the phase angle criterion is used, the function indicates whether the operating quantity is within the forward or reverse operation sector or within the non-directional sector.

---

For a detailed description of the timers, see the General function block features section in this manual.

<tr>
<td>(3) Inverse reset</td>
<td>x</td>
</tr>
</tbody>
</table>
The forward and reverse sectors are defined separately. The forward operation area is limited with the Min forward angle and Max forward angle settings. The reverse operation area is limited with the Min reverse angle and Max reverse angle settings.

The sector limits are always given as positive degree values.

In the forward operation area, the Max forward angle setting gives the clockwise sector and the Min forward angle setting correspondingly the anti-clockwise sector, measured from the Characteristic angle setting.

In the reverse operation area, the Max reverse angle setting gives the clockwise sector and the Min reverse angle setting correspondingly the anti-clockwise sector, measured from the complement of the Characteristic angle setting (180 degrees phase shift).

The relay characteristic angle (RCA) is set to positive if the operating current lags the polarizing quantity. It is set to negative if it leads the polarizing quantity.
Directional operation is not allowed (the setting *Allow non dir* is “False”) when the measured polarizing or operating quantities are not valid, that is, their magnitude is below the set minimum values. The minimum values can be defined with the settings *Min trip current* and *Min trip voltage*. In case of low magnitudes, the *FAULT_DIR* and *DIRECTION* outputs are set to 0 = unknown, except when the *Allow non dir* setting is “True”. In that case, the function is allowed to operate in the directional mode as non-directional, since the directional information is invalid.
The RCA_CTL input is used in compensated networks where the compensation coil sometimes can be disconnected. When the coil is disconnected, the compensated network becomes isolated and the Characteristic angle setting (φRCA) must be changed. This can be done automatically with the RCA_CTL input. Note that the RCA_CTL input only works when the Characteristic angle setting is set to exactly -90 degrees or 0 degrees. The value of the input affects the Characteristic angle setting in the following way:

<table>
<thead>
<tr>
<th>Characteristic angle setting</th>
<th>RCA_CTL = &quot;False&quot;</th>
<th>RCA_CTL = &quot;True&quot;</th>
</tr>
</thead>
<tbody>
<tr>
<td>-90°</td>
<td>φRCA = -90°</td>
<td>φRCA = 0°</td>
</tr>
<tr>
<td>0°</td>
<td>φRCA = 0°</td>
<td>φRCA = -90°</td>
</tr>
</tbody>
</table>

I₀sin(φ) and I₀cos(φ) criteria

A more modern approach to directional protection is the active or reactive current measurement. The operating characteristic of the directional operation depends on the grounding principle of the network. The I₀sin(φ) characteristic is used in an isolated network, measuring the reactive component of the fault current caused by the ground capacitance. The I₀cos(φ) characteristic is used in a compensated network, measuring the active component of the fault current.

The operation criteria I₀sin(φ) and I₀cos(φ) are selected with the Operation mode setting using the values “IoSin” or “IoCos”, respectively.

In isolated networks, I₀sin(φ) does not differ from the phase angle criterion, since the phase angle of the operating quantity is fairly close to -90 degrees. Furthermore, in completely compensated networks the fault current is usually mostly resistive. Therefore, the phase angle and I₀cos(φ) criteria are equally sensitive. However, if the fault is in the background network, the fault current of a sound and healthy line is almost fully capacitive and its phase angle is close to the operation area of the component. Therefore, the I₀cos(φ) characteristic is recommended, since the risk of faulty operation is smaller than with the phase angle criterion.

The angle correction setting can be used to improve selectivity. The setting decreases the operation sector. The correction can only be used with the I₀sin(φ) or I₀cos(φ) criterion. The RCA_CTL input is used to change the I₀ characteristic:

<table>
<thead>
<tr>
<th>Operation criteria:</th>
<th>RCA_CTL = &quot;False&quot;</th>
<th>RCA_CTL = &quot;True&quot;</th>
</tr>
</thead>
<tbody>
<tr>
<td>I₀sin(φ)</td>
<td>Actual operation criterion: I₀sin(φ)</td>
<td>Actual operation criterion: I₀cos(φ)</td>
</tr>
<tr>
<td>I₀cos(φ)</td>
<td>Actual operation criterion: I₀cos(φ)</td>
<td>Actual operation criterion: I₀sin(φ)</td>
</tr>
</tbody>
</table>

When the I₀sin(φ) or I₀cos(φ) criterion is used, the component indicates a forward or reverse-type fault through the FAULT_DIR and DIRECTION outputs, in which 1 equals a forward fault and 2 equals a reverse fault. Directional operation is not allowed (the Allow non dir setting is “False”) when the measured polarizing or operating quantities are not valid, that is, when their magnitude is below the set minimum values. The minimum values can be defined with the Min trip current and Min trip voltage settings. In case of low
magnitude, the `FAULT_DIR` and `DIRECTION` outputs are set to 0 = unknown, except when the
`Allow non dir` setting is “True”. In that case, the function is allowed to operate in
the directional mode as non-directional, since the directional information is invalid.

The calculated \( I_0 \sin(\varphi) \) or \( I_0 \cos(\varphi) \) current used in direction determination can be read
through the `I_OPER` monitored data. The value can be passed directly to a decisive
element, which provides the final pickup and trip signals.

The `I_OPER` monitored data gives an absolute value of the calculated
current. Otherwise, the value of a current in a reverse area is negative.

The following examples show the characteristics of the different operation criteria:

**Example 1.**

\( I_0 \sin(\varphi) \) criterion selected, forward-type fault

\[ \Rightarrow \text{FAULT_DIR} = 1 \]

**Example 2.**

\( I_0 \sin(\varphi) \) criterion selected, reverse-type fault

The operating sector is limited by Angle correction, that is, the operating sector is 180
degrees - 2*(Angle correction).

**Figure 66:** Operating characteristic \( I_0 \sin(\varphi) \) in forward fault

The following examples show the characteristics of the different operation criteria:
Section 4
Protection functions

$\Rightarrow \text{FAULT\_DIR} = 2$

$\varphi_{RCA} = -90$ deg

Figure 67: Operating characteristic $I_0 \sin(\varphi)$ in reverse fault

Example 3.
$I_0 \cos(\varphi)$ criterion selected, forward-type fault

$\Rightarrow \text{FAULT\_DIR} = 1$
Figure 68: **Operating characteristic $I_0 \cos(\varphi)$ in forward fault**

**Example 4.**

$I_0 \cos(\varphi)$ criterion selected, reverse-type fault

$\Rightarrow$ FAULT_DIR = 2
Phase angle, classic 80

The operation criterion phase angle classic 80 is selected with the Operation mode setting using the value “Phase angle 80”.

Phase angle classic 80 implements the same functionality as the phase angle, but with the following differences:

- The Max forward angle and Max reverse angle settings are not settable but have a fixed value of 80 degrees
- The sector limits of the fixed sectors are rounded.

The sector rounding is used for cancelling the CT measurement errors at low current amplitudes. When the current amplitude falls below three percent of the nominal current, the sector is reduced to 70 degrees at the fixed sector side. This makes the protection more selective, which means that the phase angle measurement errors do not cause faulty operation.

There is no sector rounding on the other side of the sector.

If the current amplitude falls below one percent of the nominal current, the direction enters the non-directional area.
Phase angle, classic 88

The operation criterion phase angle classic 88 is selected with the Operation mode setting using the value “Phase angle 88”.

Phase angle classic 88 implements the same functionality as the phase angle, but with the following differences:
The Max forward angle and Max reverse angle settings are not settable, but have a fixed value of 88 degrees. The sector limits of the fixed sectors are rounded.

Sector rounding in the phase angle classic 88 consists of three parts:

- If the current amplitude is between 1...20 percent of the nominal current, the sector limit increases linearly from 73 degrees to 85 degrees.
- If the current amplitude is between 1...100 percent of the nominal current, the sector limit increases linearly from 85 degrees to 88 degrees.
- If the current amplitude is more than 100 percent of the nominal current, the sector limit is 88 degrees.

There is no sector rounding on the other side of the sector.

If the current amplitude falls below one percent of the nominal current, the direction enters the non-directional area.

**Figure 72:** Operating characteristic for phase angle classic 88

4.1.4.9 Application

The directional ground-fault protection (67/51N and 67/50N) is designed for protection and clearance of ground faults and for ground-fault protection of different equipment connected to the power systems, such as shunt capacitor banks or shunt reactors, and for backup ground-fault protection of power transformers.

Many applications require several steps using different current start levels and time delays. 67/51N and 67/50N consists of two different stages:

- low (67/51N and 67/50N-1)
- high (67/50N-2)

67/51N and 67/50N-1 contain several types of time delay characteristics. 67/50N-2 is used for fast clearance of serious ground faults.

The protection can be based on the phase angle criterion with extended operating sector. It can also be based on measuring either the reactive part $I_0\sin(\varphi)$ or the active part $I_0\cos(\varphi)$ of the zero sequence current. In isolated networks or in networks with high impedance grounding, the phase-to-ground fault current is significantly smaller than the short-circuit currents. In addition, the magnitude of the fault current is almost independent of the fault location in the network.

The function uses the zero sequence current components $I_0\cos(\varphi)$ or $I_0\sin(\varphi)$ according to the grounding method, where $\varphi$ is the angle between the zero sequence current and the reference zero sequence voltage ($-V_0$). In compensated networks, the phase angle criterion with extended operating sector can also be used. When the relay characteristic angle RCA is 0 degrees, the negative quadrant of the operation sector can be extended with the Min forward angle setting. The operation sector can be set between 0 and -180 degrees, so that the total operation sector is from +90 to -180 degrees. In other words, the sector can be up to 270 degrees wide. This allows the protection settings to stay the same when the resonance coil is disconnected from between the neutral point and ground.
System neutral grounding is meant to protect personnel and equipment and to reduce interference for example in telecommunication systems. The neutral grounding creates challenges for protection systems, especially for ground-fault protection.

In isolated networks, there is no intentional connection between the system neutral point and ground. The only connection is through the line-to-ground capacitances \( (C_0) \) of phases and leakage resistances \( (R_0) \). This means that the zero sequence current is mainly capacitive and has \(-90^\circ\) phase shift compared to the zero sequence voltage \((-V_0)\). The characteristic angle is \(-90^\circ\).

In resonance-grounded networks, the capacitive fault current and the inductive resonance coil current compensate each other. The protection cannot be based on the reactive current measurement, since the current of the compensation coil would disturb the operation of the relays. In this case, the selectivity is based on the measurement of the active current component. This means that the zero sequence current is mainly resistive and has zero phase shift compared to the zero sequence voltage \((-V_0)\) and the characteristic angle is 0 degrees. Often the magnitude of this component is small, and must be increased by means of a parallel resistor in the compensation equipment.

In networks where the neutral point is grounded through low resistance, the characteristic angle is also 0 degrees (for phase angle). Alternatively, \( I_0 \cos(\phi) \) operation can be used.

In solidly grounded networks, the \textit{Characteristic angle} is typically set to \(+60^\circ\) for the phase angle. Alternatively, \( I_0 \sin(\phi) \) operation can be used with a reversal polarizing quantity. The polarizing quantity can be rotated 180 degrees by setting the \textit{Pol reversal} parameter to “True” or by switching the polarity of the zero sequence voltage measurement wires. Although the \( I_0 \sin(\phi) \) operation can be used in solidly grounded networks, the phase angle is recommended. In some applications, negative sequence polarization is preferred over zero sequence polarization. The relay also offers negative sequence polarization option where users can set the angle between \( V_2 \) and \( I_2 \) based on their application and practice.

**Connection of measuring transformers in directional ground fault applications**

The zero sequence current \( I_0 \) can be measured with a core balance current transformer or the residual connection of the phase current signals. If the neutral of the network is either isolated or grounded with high impedance, a core balance current transformer is recommended to be used in ground-fault protection. To ensure sufficient accuracy of zero sequence current measurements and consequently the selectivity of the scheme, the core balance current transformers should have a transformation ratio of at least 70:1. Lower transformation ratios such as 50:1 or 50:5 are not recommended.

Attention should be paid to make sure the measuring transformers are connected correctly so that 67/51N and 67/50N is able to detect the fault current direction without failure. As directional ground fault uses zero sequence current and zero sequence voltage \((-V_0)\), the polarities of the measuring transformers must match each other and also the fault current direction. Also the grounding of the cable sheath must be taken into consideration when using core balance current transformers. The following figure describes how measuring transformers can be connected to the relay.

4.1.5.2 Function block

![Function block diagram]

**Figure 75:** Function block

4.1.5.3 Functionality

A small percentage of the ground faults have very large impedance. It is possible to detect these faults by using a very sensitive earth-fault protection. It is applicable for networks where normal unbalance current level is low enough to allow for sensitive setting of 50SEF.

The function also contains a blocking functionality. It is possible to block function outputs.

4.1.5.4 Principle of operation

Same as 51N as described in 4.1.3.4 above.

4.1.5.5 Measurement modes

Same as 51N as described in 4.1.3.5 above.

4.1.5.6 Timer characteristics

Same as 51N as described in 4.1.3.6 above.

4.1.5.7 Application

Electric power lines experience faults for many reasons. In most cases, electrical faults manifest in mechanical damage, which must be repaired before returning the line to service.

Most of these faults are ground faults. A small percentage of the ground faults have a very large impedance. They are comparable to load impedance and consequently have very little fault current. These high impedance faults do not pose imminent danger to power system equipment. However, they are a considerable threat to people and property. If the natural unbalance in the system is low, the sensitive earth-fault protection can be used to detect the ground fault.

4.1.5.8 Signals

Same as 51N as described in 4.1.3.8 above.

4.1.5.9 Settings

Same as 51N as described in 4.1.3.9 above.

4.1.5.10 Monitored data

Same as 51N as described in 4.1.3.10 above.

4.1.5.11 Technical data

Same as 50N as described in 4.1.3.11 above.
4.1.6 Negative phase-sequence current protection 46

4.1.6.1 Identification

4.1.6.2 Function block

![Function block diagram]

*Figure 76: Function block*

4.1.6.3 Functionality

The negative sequence current protection 46 is used for increasing sensitivity to detect single phasing situations, unbalanced loads due to, for example, unsymmetrical feeder voltages.

46 can also be used for detecting broken conductors.

The function is based on the measurement of the negative sequence current. In a fault situation, the function picks up when the negative sequence current exceeds the set limit. The trip time characteristics can be selected to be either definite time (DT) or inverse definite minimum time (IDMT). In the DT mode, the function trips after a predefined trip time and resets when the fault current disappears. The IDMT mode provides current dependent timer characteristics.

The function contains a blocking functionality. It is possible to block function outputs, timers, or the function itself, if desired.

4.1.6.4 Operation principle

The function can be enabled and disabled with the *Operation* setting. The corresponding parameter values are Enable and Disable.

The operation of negative phase-sequence current protection can be described by using a module diagram. All the blocks in the diagram are explained in the next sections.
**Level detector**

The measured negative phase-sequence current is compared with the set *Pickup value*. If the measured value exceeds the set *Pickup value*, the level detector activates the timer module. If the ENA_MULT input is active, the set *Pickup value* is multiplied by the set *Pickup value Mult*.

---

Do not set the multiplier setting *Pickup value Mult* higher than necessary. If the value is too high, the function may not trip at all during an inrush followed by a fault, no matter how severe the fault is.

---

The relay does not accept the Pickup value or Pickup value Mult setting if the product of these settings exceeds the Pickup value setting range.

**Timer**

Once activated, the timer activates the PICKUP output. Depending on the value of the *Operating curve type* setting, the time characteristics are according to DT or IDMT. When the operation timer has reached the value of *Trip delay time* in the DT mode or the maximum value defined by the inverse time curve and the *Time adder* time has expired, the TRIP output is activated.

When the user programmable IDMT curve is selected, the operate time characteristics are defined by the parameters Curve parameter A, Curve parameter B, Curve parameter C, Curve parameter D and Curve parameter E.

If a drop-off situation happens, that is, a fault suddenly disappears before the trip delay is exceeded, the timer reset state is activated. The functionality of the timer in the reset state depends on the combination of the *Operating curve type*, *Type of reset curve* and *Reset delay time* settings. When the DT characteristic is selected, the reset timer runs until the set *Reset delay time* value is exceeded. When the IDMT curves are selected, the *Type of reset curve* setting can be set to “Immediate”, “Def time reset” or “Inverse reset”. The reset curve type “Immediate” causes an immediate reset. With the reset curve type “Def time reset”, the reset time depends on the *Reset delay time* setting. With the reset curve
type “Inverse reset”, the reset time depends on the current during the drop-off situation. If the drop-off situation continues, the reset timer is reset and the PICKUP output is deactivated.

The “Inverse reset” selection is only supported with ANSI or user programmable types of the IDMT operating curves. If another operating curve type is selected, an immediate reset occurs during the drop-off situation.

The setting Time multiplier is used for scaling the IDMT trip and reset times.

The setting parameter Minimum trip time defines the minimum desired trip time for IDMT. The setting is applicable only when the IDMT curves are used.

The Minimum trip time setting should be used with great care because the operation time is according to the IDMT curve, but always at least the value of the Minimum operate time setting. For more information, see the General function block features section in this manual.

The timer calculates the pickup duration (PICKUP_DUR) value which indicates the percentual ratio of the pickup situation and the set trip time. The value is available through the Monitored data view.

Blocking logic

There are three operation modes in the blocking functionality. The operation modes are controlled by the BLOCK input and the global setting “Configuration/System/Blocking mode” which selects the blocking mode. The BLOCK input can be controlled by a binary input, a horizontal communication input or an internal signal of the relay program. The influence of the BLOCK signal activation is preselected with the global setting Blocking mode.

The Blocking mode setting has three blocking methods. In the “Freeze timers” mode, the trip timer is frozen to the prevailing value. In the “Block all” mode, the whole function is blocked and the timers are reset. In the “Block TRIP output” mode, the function operates normally, however the TRIP output is not activated.

4.1.6.5 Application

Since the negative sequence current quantities are not present during normal, balanced load conditions, the negative sequence overcurrent protection elements can be set for faster and more sensitive operation than the normal phase-overcurrent protection for fault conditions occurring between two phases. The negative sequence overcurrent protection also provides a back-up protection functionality for the feeder ground-fault protection in solid and low resistance grounded networks.

The negative sequence overcurrent protection provides the back-up ground-fault protection on the high voltage side of a delta-wye connected power transformer for ground faults taking place on the wye-connected low voltage side. If a ground fault occurs on the wye-connected side of the power transformer, negative sequence current quantities appear on the delta-connected side of the power transformer.
Multiple time curves and time multiplier settings are also available for coordinating with other devices in the system.

</tbody>
</table>

4.1.7.2 Function block

![Function block diagram]

*Figure 78: Function block*

4.1.7.3 Functionality

The phase discontinuity protection 46PD is used for detecting unbalance situations caused by broken conductors.

The function picks up and trips when the unbalance current $I_2/I_1$ exceeds the set limit. To prevent faulty operation at least one phase current needs to be above the minimum level. 46PD trips with DT characteristic.

The function contains a blocking functionality. It is possible to block the function output, timer or the function itself, if desired.

4.1.7.4 Operation principle

The function can be enabled and disabled with the Operation setting. The corresponding parameter values are Enable and Disable.

The operation of phase discontinuity protection can be described by using a module diagram. All the blocks in the diagram are explained in the next sections.
**Figure 79:** Functional module diagram. $I_1$ and $I_2$ represent positive and negative phase sequence currents. $I_A$, $I_B$ and $I_C$ represent phase currents.

### I$_2$/I$_1$

The $I_2/I_1$ module calculates the ratio of the negative and positive phase sequence current. It reports the calculated value to the level detector.

### Level detector

The level detector compares the calculated ratio of negative and positive phase sequence currents with the set *Pickup value*. If the calculated value exceeds the set *Pickup value* and the min current check module has exceeded the minimum phase current limit, the level detector activates the timer.

### Min current check

The min current check module checks whether the measured phase currents are above the set *Min phase current*. At least one of the phase currents needs to be above the set limit to enable the level detector module.

### Timer

Once activated, the timer activates the PICKUP output. The time characteristic is according to DT. When the trip timer has reached the value set by *Trip delay time*, the TRIP output is activated. If the fault disappears before the module trips, the reset timer is activated. If the reset timer reaches the value set by *Reset delay time*, the trip timer resets and the PICKUP output is deactivated.

The timer calculates the pickup duration (PICKUP_DUR) value which indicates the ratio of the pickup situation and the set trip time. The value is available through the Monitored data view.

### Blocking logic

There are three operation modes in the blocking functionality. The operation modes are controlled by the BLOCK input and the global setting “Configuration/System/Blocking mode” which selects the blocking mode. The BLOCK input can be controlled by a binary...
input, a horizontal communication input or an internal signal of the relay program. The influence of the BLOCK signal activation is preselected with the global setting Blocking mode.

The Blocking mode setting has three blocking methods. In the “Freeze timers” mode, the trip timer is frozen to the prevailing value. In the “Block all” mode, the whole function is blocked and the timers are reset. The “Block TRIP output” mode, the function operates normally but the TRIP output is not activated.

4.1.7.5 Application

In three-phase distribution and subtransmission network applications the phase discontinuity in one phase can cause increase of zero sequence voltage and short overvoltage peaks and also oscillation in the corresponding phase.

46PD is a three-phase protection with DT characteristic, designed for detecting broken conductors in distribution and subtransmission networks. The function is applicable for both overhead lines and underground cables.

The operation of 46PD is based on the ratio of positive and negative sequence currents. This gives better sensitivity and stability compared to plain negative sequence current protection since the calculated ratio of positive and negative sequence currents is relatively constant during load variations.

When the three phase currents are measured, the positive sequence current is calculated:

\[ I_1 = \frac{1}{3}(I_a + aI_b + a^2I_c) \]  
(Equation 28)

The negative sequence current is calculated:

\[ I_2 = \frac{1}{3}(I_a + a^2I_b + aI_c) \]  
(Equation 29)

\( I_a, I_b, I_c \) phase current vectors

\( a \) phase rotation operator (defined to rotate a phasor component forward by 120 degrees)

The unbalance of the network is detected by monitoring the negative and positive sequence current ratio, where the negative sequence current value is \( I_2 \) and \( I_1 \) is the positive sequence current value. The unbalance is calculated:

\[ Iratio = \frac{I_2}{I_1} \]  
(Equation 30)

Broken conductor fault situation can occur in phase A in a feeder.
Figure 80: Broken conductor fault in phase A in a distribution or subtransmission feeder

Figure 81: Three-phase current quantities during the broken conductor fault in phase A with the ratio of negative and positive sequence currents

4.1.8.2 Function block

![Function block diagram](image)

*Figure 82: Function block*

4.1.8.3 Functionality

The transformer inrush detection INR is used to coordinate transformer inrush situations in distribution networks.

Transformer inrush detection is based on the following principle: the output signal BLK2H is activated once the numerically derived ratio of second harmonic current I_2H and the fundamental frequency current I_1H exceeds the set value.

The trip time characteristic for the function is of definite time (DT) type.

The function contains a blocking functionality. Blocking deactivates all outputs and resets timers.

4.1.8.4 Operation principle

The function can be enabled and disabled with the *Operation* setting. The corresponding parameter values are Enable and Disable.

The operation of an inrush current detection function can be described by using a module diagram. All the blocks in the diagram are explained in the next sections.
**Protection functions**

**Figure 83:** Functional module diagram. $I_{1H}$ and $I_{2H}$ represent fundamental and second harmonic values of phase currents.

### $I_{2H}/I_{1H}$

This module calculates the ratio of the second harmonic ($I_{2H}$) and fundamental frequency ($I_{1H}$) phase currents. The calculated value is compared with the set *Pickup value*. If the calculated value exceeds the set *Pickup value*, the module output is activated.

### Level detector

The output of the phase specific level detector is activated when the fundamental frequency current $I_{1H}$ exceeds five percent of the nominal current.

### Timer

Once activated, the timer runs until the set *Trip delay time* value. The time characteristic is according to DT. When the trip timer has reached the *Trip delay time* value, the $BLK2H$ output is activated. After the timer has elapsed and the inrush situation still exists, the $BLK2H$ signal remains active until the $I_{2H}/I_{1H}$ ratio drops below the value set for the ratio in all phases, that is, until the inrush situation is over. If the drop-off situation occurs within the trip time up counting, the reset timer is activated. If the drop-off time exceeds *Reset delay time*, the trip timer is reset.

The $BLOCK$ input can be controlled with a binary input, a horizontal communication input or an internal signal of the relay program. The activation of the $BLOCK$ input prevents the $BLK2H$ output from being activated.

It is recommended to use the second harmonic and the waveform based inrush blocking from the transformer differential protection function 87T if available.
4.1.8.5 Application

Transformer protections require high stability to avoid tripping during magnetizing inrush conditions. A typical example of an inrush detector application is doubling the pickup value of an overcurrent protection during inrush detection.

The inrush detection function can be used to selectively block overcurrent and ground-fault function stages when the ratio of second harmonic component over the fundamental component exceeds the set value.

Other applications of this function include the detection of inrush in lines connected to a transformer.

*Figure 84: Inrush current in transformer*

It is recommended to use the second harmonic and the waveform based inrush blocking from the transformer differential protection function 87T if available.

4.3.1.2 Function block

![Function block diagram]

**Figure 85:** Function block

4.3.1.3 Functionality

The single-phase overvoltage protection 59 is applied on power system elements, such as generators, transformers, motors and power lines, to protect the system from excessive voltages that could damage the insulation and cause insulation breakdown. The three-phase overvoltage function includes a settable value for the detection of overvoltage either in a single phase, two phases or three phases.

59 includes both definite time (DT) and inverse definite minimum time (IDMT) characteristics for the delay of the trip.

The function contains a blocking functionality. It is possible to block function outputs, timer or the function itself, if desired.

4.3.1.4 Operation principle

The function can be enabled and disabled with the Operation setting. The corresponding parameter values are Enable and Disable.

The operation of the single-phase overvoltage protection can be described by using a module diagram. All the modules in the diagram are explained in the next sections.
Figure 86: Functional module diagram (Three Phase trip mode)

Three Phase Mode

The following description holds good when three phase mode is chosen for the recloser.

The fundamental frequency component of the measured single-phase voltage is compared to the set value of the *Start (pickup) value* setting phase-wise. If the measured value is higher than the set value of the *Pickup value* setting, the level detector enables the phase selection logic module. The *Relative hysteresis* setting can be used for preventing unnecessary oscillations if the input signal slightly differs from the *Pickup value* setting. After leaving the hysteresis area, the pickup condition has to be fulfilled again and it is not sufficient for the signal to only return to the hysteresis area.

The *Voltage selection* setting is used for selecting phase-to-ground or phase-to-phase voltages for protection.

For the voltage IDMT operation mode, the used IDMT curve equations contain discontinuity characteristics. The *Curve Sat relative* setting is used for preventing undesired operation.

For a more detailed description of the IDMT curves and the use of the *Curve Sat Relative* setting, see the General function block features section in this manual.

Phase selection logic

If the fault criteria are fulfilled in the level detector, the phase selection logic detects the phase or phases in which the fault level is detected. If the number of faulty phases match with the set *Num of start phases*, the phase selection logic activates the timer.

Timer

Once activated, the timer activates the *PICKUP (START)* output. Depending on the value of the set *Operating curve type*, the time characteristics are selected according to DT or IDMT.

For a detailed description of the voltage IDMT curves, see the General function block features section in this manual.
When the operation timer has reached the value set by Trip delay time in the DT mode or the maximum value defined by the IDMT, the TRIP (OPERATE) output is activated.

When the user-programmable IDMT curve is selected, the trip time characteristics are defined by the parameters Curve parameter A, Curve parameter B, Curve parameter C, Curve parameter D and Curve parameter E.

If a drop-off situation occurs, that is, a fault suddenly disappears before the trip delay is exceeded, the reset state is activated. The behavior in the drop-off situation depends on the selected trip time characteristics. If the DT characteristics are selected, the reset timer runs until the set Reset delay time value is exceeded. If the drop-off situation exceeds the set Reset delay time, the timer is reset and the PICKUP output is deactivated.

When the IDMT trip time curve is selected, the functionality of the timer in the drop-off state depends on the combination of the Type of reset curve and Reset delay time settings.

**Single Phase Mode**

![Functional module diagram](image)

*Figure 87: Functional module diagram (Single Phase)*

The following description holds good when single phase mode is chosen for the recloser.

The fundamental frequency component of the measured single-phase voltage is compared to the set value of the Start (pickup) value setting phase-wise. The Relative hysteresis setting can be used for preventing unnecessary oscillations if the input signal slightly differs from the Pickup value setting. After leaving the hysteresis area, the pickup condition has to be fulfilled again and it is not sufficient for the signal to only return to the hysteresis area.

The Voltage selection setting is used for selecting phase-to-ground or phase-to-phase voltages for protection.

For the voltage IDMT operation mode, the used IDMT curve equations contain discontinuity characteristics. The Curve Sat relative setting is used for preventing undesired operation.

For a more detailed description of the IDMT curves and the use of the Curve Sat Relative setting, see the General function block features section in this manual.
Timer

Once activated, the timer activates the respective phase \texttt{PICKUP(ST\_A\_AB)} as shown typically above for respective phase output as well as the common \texttt{PICKUP} (\texttt{START}) output. Depending on the value of the set \textit{Operating curve type}, the time characteristics are selected according to DT or IDMT.

For a detailed description of the voltage IDMT curves, see the General function block features section in this manual.

When the operation timer has reached the value set by \textit{Trip delay time} in the DT mode or the maximum value defined by the IDMT, the \texttt{TRIP} (\texttt{OPR\_A\_AB}) for respective phase as well as the common the \texttt{OPERATE} output are activated.

When the user-programmable IDMT curve is selected, the trip time characteristics are defined by the parameters \textit{Curve parameter A}, \textit{Curve parameter B}, \textit{Curve parameter C}, \textit{Curve parameter D} and \textit{Curve parameter E}.

If a drop-off situation occurs, that is, a fault suddenly disappears before the trip delay is exceeded, the reset state is activated. The behavior in the drop-off situation depends on the selected trip time characteristics. If the DT characteristics are selected, the reset timer runs until the set \textit{Reset delay time} value is exceeded. If the drop-off situation exceeds the set \textit{Reset delay time}, the timer is reset and the \texttt{PICKUP} output is deactivated.

When the IDMT trip time curve is selected, the functionality of the timer in the drop-off state depends on the combination of the \textit{Type of reset curve} and \textit{Reset delay time} settings.

\begin{table}[h]
\centering
\begin{tabular}{|l|l|}
\hline
\textbf{Type of reset curve} & \textbf{Description of operation} \\
\hline
"Immediate" & The trip timer is reset instantaneously when drop-off occurs \\
\hline
"Def time reset" & The trip timer is frozen during drop-off. The trip timer is reset after the set \textit{Reset delay time} is exceeded \\
\hline
"DT Lin decr rst" & The trip timer value linearly decreases during the drop-off situation. The trip timer is reset after the set \textit{Reset delay time} is exceeded \\
\hline
\end{tabular}
\caption{The reset time functionality when the IDMT trip time curve is selected}
\end{table}

Figure 88: Behavior of different IDMT reset modes. The value for Type of reset curve is “Def time reset”. Also other reset modes are presented for the time integrator.

The Time multiplier setting is used for scaling the IDMT trip times.

The Minimum operate time setting parameter defines the minimum desired trip time for IDMT. The setting is applicable only when the IDMT curves are used.

The Minimum operate time setting should be used with care because the operation time is according to the IDMT curve, but always at least the value of the Minimum operate time setting. For more information, see the General function block features section in this manual.

The timer calculates the pickup duration value PICKUP_DUR which indicates the percentage ratio of the pickup situation and the set trip time. The value is available through the Monitored data view.
Section 4
Protection functions

Blocking logic

There are three operation modes in the blocking functionality. The operation modes are controlled by the BLOCK input and the global setting Configuration > System > Blocking mode which selects the blocking mode. The BLOCK input can be controlled by a binary input, a horizontal communication input or an internal signal of the relay program. The influence of the BLOCK input signal activation is preselected with the global Blocking mode setting.

The Blocking mode setting has three blocking methods. In the “Freeze timers” mode, the operate timer is frozen to the prevailing value. In the “Block all” mode, the whole function is blocked and the timers are reset. In the “Block OPERATE output” mode, the function operates normally but the OPERATE output is not activated.

The “Freeze timers” mode of blocking has no effect during the “Inverse reset” mode.

4.3.1.5 Timer characteristics

The operating curve types supported by 59 are:

<table>
<thead>
<tr>
<th>Operating curve type</th>
</tr>
</thead>
<tbody>
<tr>
<td>(5) ANSI Def. Time</td>
</tr>
<tr>
<td>(15) IEC Def. Time</td>

<td>(18) Inv. Curve B</td>
</tr>
<tr>
<td>(19) Inv. Curve C</td>
</tr>
<tr>
<td>(20) Programmable</td>
</tr>
</tbody>
</table>

4.3.1.6 Application

Overvoltage in a network occurs either due to the transient surges on the network or due to prolonged power frequency overvoltages. Surge arresters are used to protect the network against the transient overvoltages, but the relay protection function is used to protect against power frequency overvoltages.

The power frequency overvoltage may occur in the network due to the contingencies such as:

- The defective operation of the automatic voltage regulator when the generator is in isolated operation.
- Operation under manual control with the voltage regulator out of service. A sudden variation of load, in particular the reactive power component, gives rise to a substantial change in voltage because of the inherent large voltage regulation of a typical alternator.
- Sudden loss of load due to the tripping of outgoing feeders, leaving the generator isolated or feeding a very small load. This causes a sudden rise in the terminal voltage due to the trapped field flux and overspeed.
If a load sensitive to overvoltage remains connected, it leads to equipment damage.

It is essential to provide power frequency overvoltage protection, in the form of time delayed element, either IDMT or DT to prevent equipment damage.

4.3.2.2 Function block

![Function block diagram]

Figure 89: Function block
4.3.2.3 Functionality

The three-phase undervoltage protection (27) is used to disconnect from the network devices, for example electric motors, which are damaged when subjected to service under low voltage conditions. The 27 function includes a settable value for the detection of undervoltage either in a single phase, two phases, or three phases.

The function contains a blocking functionality. It is possible to block function outputs, timer, or the function itself, if desired.

4.3.2.4 Operation principle

The function can be enabled and disabled with the Operation setting. The corresponding parameter values are Enable and Disable.

The operation of the three-phase undervoltage protection can be described by using a module diagram. All the modules in the diagram are explained in the next sections.

![Functional module diagram](image)

**Figure 90:** Functional module diagram

### Three Phase Mode

The fundamental frequency component of the measured three phase voltages are compared phase-wise to the set Pickup value. If the measured value is lower than the set value of the Pickup value setting, the level detector enables the phase selection logic module. The Relative hysteresis setting can be used for preventing unnecessary oscillations if the input signal slightly varies above or below the Pickup value setting. After leaving the hysteresis area, the pickup condition has to be fulfilled again and it is not sufficient for the signal to only return back to the hysteresis area.

The Voltage selection setting is used for selecting the phase-to-ground or phase-to-phase voltages for protection.

For the voltage IDMT mode of operation, the used IDMT curve equations contain discontinuity characteristics. The Curve Sat relative setting is used for preventing unwanted operation.

For more detailed description on IDMT curves and usage of Curve Sat Relative setting, see the General function block features section in this manual.
The level detector contains a low-level blocking functionality for cases where one of the measured voltages is below the desired level. This feature is useful when unnecessary pickups and trips are wanted to avoid during, for example, an autoreclose sequence. The low-level blocking is activated by default (Enable block value is set to “True”) and the blocking level can be set with the Voltage block value setting.

**Phase selection logic**

If the fault criteria are fulfilled in the level detector, the phase selection logic detects the phase or phases in which the fault level is detected. If the number of faulty phases match with the set Num of pickup phases, the phase selection logic activates the timer.

**Timer**

Once activated, the timer activates the PICKUP (START) output. Depending on the value of the set Operating curve type, the time characteristics are selected according to DT or IDMT.

For a detailed description of the voltage IDMT curves, see the General function block features section in this manual.

When the operation timer has reached the value set by Trip delay time in the DT mode or the maximum value defined by the IDMT, the TRIP (OPERATE) output is activated.

When the user-programmable IDMT curve is selected, the trip time characteristics are defined by the parameters Curve parameter A, Curve parameter B, Curve parameter C, Curve parameter D and Curve parameter E.

If a drop-off situation occurs, that is, a fault suddenly disappears before the trip delay is exceeded, the reset state is activated. The behavior in the drop-off situation depends on the selected trip time characteristics. If the DT characteristics are selected, the reset timer runs until the set Reset delay time value is exceeded. If the drop-off situation exceeds the set Reset delay time, the timer is reset and the PICKUP output is deactivated.

When the IDMT trip time curve is selected, the functionality of the timer in the drop-off state depends on the combination of the Type of reset curve and Reset delay time settings.
**Section 4**

**Protection functions**

---

**Single Phase Mode**

![Functional module diagram (Single Phase)](image)

**Figure 91:** Functional module diagram (Single Phase)

The following description holds good when single phase mode is chosen for the recloser.

The fundamental frequency component of the measured single-phase voltage is compared to the set value of the Start (pickup) value setting phase-wise. The Relative hysteresis setting can be used for preventing unnecessary oscillations if the input signal slightly differs from the Pickup value setting. After leaving the hysteresis area, the pickup condition has to be fulfilled again and it is not sufficient for the signal to only return to the hysteresis area.

The Voltage selection setting is used for selecting phase-to-ground or phase-to-phase voltages for protection.

For the voltage IDMT operation mode, the used IDMT curve equations contain discontinuity characteristics. The Curve Sat relative setting is used for preventing undesired operation.

For a more detailed description of the IDMT curves and the use of the Curve Sat Relative setting, see the General function block features section in this manual.

**Timer**

Once activated, the timer activates the respective phase PICKUP(ST_A_AB) as shown typically above for respective phase output as well as the common PICKUP (START) output. Depending on the value of the set Operating curve type, the time characteristics are selected according to DT or IDMT.

For a detailed description of the voltage IDMT curves, see the General function block features section in this manual.

When the operation timer has reached the value set by Trip delay time in the DT mode or the maximum value defined by the IDMT, the TRIP (OPR_A_AB) for respective phase as well as the common the OPERATE output are activated.
When the user-programmable IDMT curve is selected, the trip time characteristics are defined by the parameters Curve parameter A, Curve parameter B, Curve parameter C, Curve parameter D and Curve parameter E.

If a drop-off situation occurs, that is, a fault suddenly disappears before the trip delay is exceeded, the reset state is activated. The behavior in the drop-off situation depends on the selected trip time characteristics. If the DT characteristics are selected, the reset timer runs until the set Reset delay time value is exceeded. If the drop-off situation exceeds the set Reset delay time, the timer is reset and the PICKUP output is deactivated.

When the IDMT trip time curve is selected, the functionality of the timer in the drop-off state depends on the combination of the Type of reset curve and Reset delay time settings.

<table>

</tr>
<tr>
<td>“DT Lin decr rst”</td>
<td>The trip timer value linearly decreases during the drop-off situation. The trip timer is reset after the set Reset delay time is exceeded</td>
</tr>
</tbody>
</table>
Example

Figure 92: Behavior of different IDMT reset modes. The value for Type of reset curve is “Def time reset”. Also other reset modes are presented for the time integrator.

The Time multiplier setting is used for scaling the IDMT trip times.

The Minimum Trip time setting parameter defines the minimum desired trip time for IDMT. The setting is applicable only when the IDMT curves are used.

The Minimum operate time setting should be used with care because the operation time is according to the IDMT curve, but always at least the value of the Minimum operate time setting. For more information, see the General function block features section in this manual.

The timer calculates the pickup duration value PICKUP_DUR which indicates the percentage ratio of the pickup situation and the set trip time. The value is available through the Monitored data view.
Block the logic

There are three operation modes in the blocking functionality. The operation modes are controlled by the BLOCK input and the global setting Configuration > System > Blocking mode which selects the blocking mode. The BLOCK input can be controlled by a binary input, a horizontal communication input or an internal signal of the relay program. The influence of the BLOCK input signal activation is preselected with the global Blocking mode setting.

The Blocking mode setting has three blocking methods. In the “Freeze timers” mode, the operate timer is frozen to the prevailing value. In the “Block all” mode, the whole function is blocked and the timers are reset. In the “Block TRIP output” mode, the function operates normally but the TRIP output is not activated.

The “Freeze timers” mode of blocking has no effect during the “Inverse reset” mode.

4.3.2.5 Timer characteristics

The operating curve types supported by 27 are:

<table>

</tr>
</tbody>
</table>

4.3.2.6 Application

27 is applied to power system elements, such as generators, transformers, motors and power lines, to detect low voltage conditions. Low voltage conditions are caused by abnormal operation or a fault in the power system. 27 can be used in combination with overcurrent protections. Other applications are the detection of a no-voltage condition, for example before the energization of a high voltage line, or an automatic breaker trip in case of a blackout. 27 is also used to initiate voltage correction measures, such as insertion of shunt capacitor banks, to compensate for a reactive load and thereby to increase the voltage.

27 can be used to disconnect from the network devices, such as electric motors, which are damaged when subjected to service under low voltage conditions. 27 deals with low voltage conditions at power system frequency. Low voltage conditions can be caused by:

- Malfunctioning of a voltage regulator or incorrect settings under manual control (symmetrical voltage decrease)
- Overload (symmetrical voltage decrease)
- Short circuits, often as phase-to-ground faults (unsymmetrical voltage increase).
27 prevents sensitive equipment from running under conditions that could cause overheating and thus shorten their life time expectancy. In many cases, 27 is a useful function in circuits for local or remote automation processes in the power system.

4.3.3.2 Function block

![Function block diagram](image)

Figure 93: Function block

4.3.3.3 Functionality

The zero sequence overvoltage protection 59N is used in distribution networks where the zero sequence overvoltage can reach non-acceptable levels in, for example, high impedance grounding.

The function picks up when the zero sequence voltage exceeds the set limit. 59N operates with the definite time (DT) characteristic.

The function contains a blocking functionality. It is possible to block function outputs, the definite timer or the function itself, if desired.
4.3.3.4 **Operation principle**

The function can be enabled and disabled with the *Operation* setting. The corresponding parameter values are Enable and Disable.

The operation of residual overvoltage protection can be described by using a module diagram. All the blocks in the diagram are explained in the next sections.

![Module diagram](image)

**Figure 94:** Functional module diagram. $V_N$ represents the zero sequence voltage.

**Level detector**

The measured or calculated zero sequence voltage is compared with the set *Pickup value*. If the value exceeds the set *Pickup value*, the level detector sends an enable-signal to the timer.

**Timer**

Once activated, the timer activates the *PICKUP* output. The time characteristic is according to DT. When the trip timer has reached the value set by *Trip delay time*, the *TRIP* output is activated. If the fault disappears before the module trips, the reset timer is activated. If the reset timer reaches the value set by *Reset delay time*, the trip timer resets and the *PICKUP* output is deactivated.

The timer calculates the pickup duration (*PICKUP\_DUR*) value which indicates the ratio of the pickup situation and the set trip time. The value is available through the Monitored data view.

**Blocking logic**

There are three operation modes in the blocking functionality. The operation modes are controlled by the *BLOCK* input and the global setting “Configuration/System/Blocking mode” which selects the blocking mode. The *BLOCK* input can be controlled by a binary input, a horizontal communication input or an internal signal of the relay program. The influence of the *BLOCK* signal activation is preselected with the global setting *Blocking mode*.

The *Blocking mode* setting has three blocking methods. In the “Freeze timers” mode, the trip timer is frozen to the prevailing value. In the “Block all” mode, the whole function is
blocked and the timers are reset. the “Block TRIP output” mode, the function operates normally but the TRIP output is not activated.

### 4.3.3.5 Application

59N is designed to be used for ground-fault protection in isolated neutral, resistance grounded or reactance grounded systems. In compensated networks, the pickup of the function can be used to control the switching device of the neutral resistor. The function can also be used for the back-up protection of feeders for busbar protection when a more dedicated busbar protection would not be justified.

In compensated and isolated neutral systems, the system neutral voltage, that is, the zero sequence voltage, increases in case of any fault connected to ground. Depending on the type of the fault and the fault resistance, the zero sequence voltage reaches different values. The highest zero sequence voltage, equal to the phase-to-ground voltage, is achieved for a single-phase ground fault. The zero sequence voltage increases approximately the same amount in the whole system and does not provide any guidance in finding the faulty component. Therefore, this function is often used as a back-up protection or as a release signal for the feeder ground-fault protection.

The protection can also be used for the ground-fault protection of generators and motors and for the unbalance protection of capacitor banks.

The zero sequence voltage can be calculated internally based on the measurement of the three-phase voltage. This voltage can also be measured by a single-phase voltage transformer, located between a transformer star point and ground, or by using an open-delta connection of three single-phase voltage transformers.

</tbody>
</table>

4.3.4.2 Function block

![Figure 95: Function block](image)

4.3.4.3 Functionality

The positive sequence voltage is constantly compared with the set value of positive sequence voltage and starts when the measured sequence voltage exceeds the *Pickup value*. If the overvoltage lasts the *Trip delay* time, the function gives the trip signal.

4.3.4.4 Operation principle

The 59PS function constantly monitors the magnitude of the positive sequence voltage. If and when the measured positive sequence voltage exceeds the *Pickup value* voltage, the PICKUP output gets activated. Should the overvoltage situation last the *Trip delay* time, the function trips through TRIP output.

The function includes *Relative hysteresis* setting in order to avoid oscillations of the PICKUP output when the measured positive sequence voltage value lies near the *Pickup value* voltage.

The delay of the heavy duty output relay is included in preset operate times (depends on the value of delay compensation).

The definite timer is allowed to run only if the input signal BLOCK is inactive. If the BLOCK signal is activated, the timer will be reset. Moreover the PICKUP and TRIP signals cannot be activated when the BLOCK signal is active.

When the output PICKUP is active, the percentage of delay time duration that has elapsed can be monitored through output PICKUPDUR of that sequence. It is possible to tune all the time delays provided in the function such that they provide delay equal to set delay within acceptable tolerance. Initialization input DLY_COM is used to provide compensation for delays caused in software and mechanical output relays. When FR_TIMER is active delay time counts are frozen, hence activation of FR_TIMER will have effect of increasing effective time delays by the time for which FR_TIMER is active.
4.3.4.5 Application

Positive sequence overvoltage protection (59PS) is used to detect positive phase sequence overvoltage conditions. The 59PS function can be used in various applications as an alternative to ordinary three-phase overvoltage protection.

4.3.4.8 Technical data

Table 227: 59PS Technical data

Characteristic                              Value
--------------------------------------------------------------------------------------
Operation accuracy                           Depending on the frequency of the voltage measured: \( f_n \pm 2\text{Hz} \)
                                              \( \pm 1.5\% \) of the set value or \( \pm 0.002 \times V_n \)

Pickup time\(^1,2\)                          \( V_{\text{Fault}} = 1.1 \times \text{set Pickup value} \)
Minimum                                       29 ms
Typical                                       31 ms
Maximum                                       32 ms
Reset time                                    < 40 ms
Reset ratio                                   Typical 0.96
Retardation time                              < 35 ms
Trip time accuracy in definite time mode      \( \pm 1.0\% \) of the set value or \( \pm 20 \text{ms} \)
Suppression of harmonics                      DFT: -50 dB at \( f = n \times f_n \), where \( n = 2, 3, 4, 5,... \)

1. Zero sequence voltage before fault = 0.0 \( \times V_n \), \( f_n = 60 \text{Hz} \), zero sequence voltage with nominal frequency injected from random phase angle, results based on statistical distribution of 1000 measurements
2. Includes the delay of the signal output contact
4.3.5 Negative sequence overvoltage protection 47

4.3.5.1 Identification

The negative-sequence overvoltage protection 47 is used to detect negative-sequence overvoltage conditions. 47 is used for the protection of machines.

4.3.5.2 Function block

The function picks up when the negative-sequence voltage exceeds the set limit. 47 operates with the definite time (DT) characteristics.

4.3.5.3 Functionality

The function contains a blocking functionality. It is possible to block function outputs, the definite timer or the function itself, if desired.

4.3.5.4 Operation principle

The function can be enabled and disabled with the Operation setting. The corresponding parameter values are Enable and Disable.

The operation of negative sequence overvoltage protection can be described by using a module diagram. All the blocks in the diagram are explained in the next sections.

![Functional module diagram](image)

Figure 98: Functional module diagram. $V_2$ is used for representing negative phase sequence voltage.

**Level detector**

The calculated negative sequence voltage is compared with the set Pickup value setting. If the value exceeds the set Pickup value, the level detector enables the timer.
Section 4  
Protection functions

Timer

Once activated, the timer activates the PICKUP output. The time characteristic is according to DT. When the operation timer has reached the value set by Operate delay time, the OPERATE output is activated if the overvoltage condition persists. If the negative sequence voltage normalizes before the module operates, the reset timer is activated. If the reset timer reaches the value set by Reset delay time, the operate timer resets and the PICKUP output is deactivated.

The timer calculates the pickup duration (PICKUP_DUR) value which indicates the ratio of the pickup situation and the set trip time. The value is available through the Monitored data view.

Blocking logic

There are three operation modes in the blocking functionality. The operation modes are controlled by the BLOCK input and the global setting “Configuration/System/Blocking mode” which selects the blocking mode. The BLOCK input can be controlled by a binary input, a horizontal communication input or an internal signal of the relay program. The influence of the BLOCK signal activation is preselected with the global setting Blocking mode.

The Blocking mode setting has three blocking methods. In the “Freeze timers” mode, the trip timer is frozen to the prevailing value. In the “Block all” mode, the whole function is blocked and the timers are reset. the “Block TRIP output” mode, the function operates normally but the TRIP output is not activated.

4.3.5.5 Application

A continuous or temporary voltage unbalance can appear in the network for various reasons. The voltage unbalance mainly occurs due to broken conductors or asymmetrical loads and is characterized by the appearance of a negative-sequence component of the voltage. In rotating machines, the voltage unbalance results in a current unbalance, which heats the rotors of the machines. The rotating machines, therefore, do not tolerate a continuous negative-sequence voltage higher than typically 1-2 percent x V_n.

The negative-sequence component current I_2, drawn by an asynchronous or a synchronous machine, is linearly proportional to the negative-sequence component voltage V_2. When V_2 is P% of V_n, I_2 is typically about 5 x P% x I_n.

The negative-sequence overcurrent 46 blocks are used to accomplish a selective protection against the voltage and current unbalance for each machine separately. Alternatively, the protection can be implemented with the 47 function, monitoring the voltage unbalance of the busbar.

If the machines have an unbalance protection of their own, the 47 operation can be applied as a backup protection or it can be used as an alarm. The latter can be applied when it is not required to trip loads tolerating voltage unbalance better than the rotating machines.

If there is a considerable degree of voltage unbalance in the network, the rotating machines should not be connected to the network at all. This logic can be implemented by inhibiting
the closure of the circuit breaker if the 47 operation has started. This scheme also prevents connecting the machine to the network if the phase sequence of the network is not correct.

An appropriate value for the setting parameter *Voltage pickup value* is approximately 3 percent of $V_n$. A suitable value for the setting parameter *Trip delay time* depends on the application. If the 47 operation is used as a backup protection, the trip time should be set in accordance with the trip time of 46 used as the main protection. If the 47 operation is used as the main protection, the trip time should be approximately one second.

4.4.1.2 Function block

![Function block diagram](image)

4.4.1.3 Functionality

The frequency protection functions (81O/81U, 81R) are used to protect network components against abnormal frequency conditions.

The function provides basic overfrequency, underfrequency and frequency rate of change protection. Additionally, it is possible to use combined criteria to achieve even more sophisticated protection schemes for the system.

The function contains a blocking functionality. It is possible to block function outputs, timer or the function itself, if desired.

4.4.1.4 Operation principle

The function can be enabled and disabled with the Operation setting. The corresponding parameter values are “On” and “Off”.

The operation of the frequency protection function can be described using a module diagram. All the modules in the diagram are explained in the next sections.
Protection functions

Section 4

Figure 100: Functional module diagram

Freq>/< detection

The frequency detection module includes an overfrequency or underfrequency detection based on the Operation mode setting.

In the “Freq>” mode, the measured frequency is compared to the set Pickup value Freq>. If the measured value exceeds the set value of the Start value Freq> setting, the module reports the exceeding of the value to the operate logic module.

In the “Freq<” mode, the measured frequency is compared to the set Pickup value Freq<. If the measured value is lower than the set value of the Start value Freq< setting, the module reports the value to the operate logic module.

df/dt detection

The frequency gradient detection module includes a detection for a positive or negative rate-of-change (gradient) of frequency based on the set Start value df/dt value. The negative rate-of-change protection is selected when the set value is negative. The positive rate-of-change protection is selected when the set value is positive. When the frequency gradient protection is selected and the gradient exceeds the set Pickup value df/dt value, the module reports the exceeding of the value to the operate logic module.

The relay does not accept the set value “0.00” for the Pickup value df/dt setting.

Operate logic

This module is used for combining different protection criteria based on the frequency and the frequency gradient measurement to achieve a more sophisticated behavior of the function. The criteria are selected with the Operation mode setting.
### Table 234: Operation modes for operation logic

<table>
<thead>
<tr>
<th>Operation mode</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Freq&lt;</td>
<td>The function operates independently as the underfrequency (&quot;Freq&lt;&quot;) protection function. When the measured frequency is below the set value of the <em>Start value Freq&lt;</em> setting, the module activates the <strong>START</strong> and <strong>STR_UFRQ</strong> outputs. The time characteristic is according to DT. When the operation timer has reached the value set by the <strong>Operate Tm Freq</strong> setting, the OPERATE and <strong>OPR_UFRQ</strong> outputs are activated. If the frequency restores before the module operates, the reset timer is activated. If the timer reaches the value set by the <strong>Reset delay Tm Freq</strong> setting, the operate timer resets and the <strong>START</strong> and <strong>STR_UFRQ</strong> outputs are deactivated.</td>
</tr>
<tr>
<td>Freq&gt;</td>
<td>The function operates independently as the overfrequency (&quot;Freq&gt;&quot;) protection function. When the measured frequency exceeds the set value of the <em>Start value Freq&gt;</em> setting, the module activates the <strong>START</strong> and <strong>STR_OFRQ</strong> outputs. The time characteristic is according to DT. When the operation timer has reached the value set by the <strong>Operate Tm Freq</strong> setting, the OPERATE and <strong>OPR_OFRQ</strong> outputs are activated. If the frequency restores before the module operates, the reset timer is activated. If the timer reaches the value set by the <strong>Reset delay Tm Freq</strong> setting, the operate timer resets and the <strong>START</strong> and <strong>STR_OFRQ</strong> outputs are deactivated.</td>
</tr>
<tr>
<td>df/dt</td>
<td>The function operates independently as the frequency gradient (&quot;df/dt&quot;), rate-of-change, protection function. When the frequency gradient exceeds the set value of the <em>Start value df/dt</em> setting, the module activates the <strong>START</strong> and <strong>STR_FRG</strong> outputs. The time characteristic is according to DT. When the operation timer has reached the value set by the <strong>Operate Tm df/dt</strong> setting, the OPERATE and <strong>OPR_FRG</strong> outputs are activated. If the frequency gradient restores before the module operates, the reset timer is activated. If the timer reaches the value set by the <strong>Reset delay Tm df/dt</strong> setting, the operate timer resets and the <strong>START</strong> and <strong>STR_FRG</strong> outputs are deactivated. The <strong>OPR_UFRQ</strong> output is not active when this operation mode is used.</td>
</tr>
<tr>
<td>Freq&lt; + df/dt</td>
<td>A consecutive operation is enabled between the protection methods. When the measured frequency is below the set value of the <em>Start value Freq&lt;</em> setting, the frequency gradient protection is enabled. After the frequency has dropped below the set value, the frequency gradient is compared to the set value of the <em>Start value df/dt</em> setting. When the frequency gradient exceeds the set value, the module activates the <strong>START</strong> and <strong>STR_FRG</strong> outputs. The time characteristic is according to DT. When the operation timer has reached the value set by the <strong>Operate Tm df/dt</strong> setting, the OPERATE and <strong>OPR_FRG</strong> outputs are activated. If the frequency gradient restores before the module operates, the reset timer is activated. If the timer reaches the value set by the <strong>Reset delay Tm df/dt</strong> setting, the operate timer resets and the <strong>START</strong> and <strong>STR_FRG</strong> outputs are deactivated. The <strong>OPR_UFRQ</strong> output is not active when this operation mode is used.</td>
</tr>
<tr>
<td>Freq&gt; + df/dt</td>
<td>A consecutive operation is enabled between the protection methods. When the measured frequency exceeds the set value of the <em>Start value Freq&gt;</em> setting, the frequency gradient protection is enabled. After the frequency exceeds the set value, the frequency gradient is compared to the set value of the <em>Start value df/dt</em> setting. When the frequency gradient exceeds the set value, the module activates the <strong>START</strong> and <strong>STR_FRG</strong> outputs. The time characteristic is according to DT. When the operation timer has reached the value set by the <strong>Operate Tm df/dt</strong> setting, the OPERATE and <strong>OPR_FRG</strong> outputs are activated. If the frequency gradient restores before the module operates, the reset timer is activated. If the timer reaches the value set by the <strong>Reset delay Tm df/dt</strong> setting, the operate timer resets and the <strong>START</strong> and <strong>STR_FRG</strong> outputs are deactivated. The <strong>OPR_OFRQ</strong> output is not active when this operation mode is used.</td>
</tr>
<tr>
<td>Freq&lt; OR df/dt</td>
<td>A parallel operation between the protection methods is enabled. The <strong>START</strong> output is activated when either of the measured values of the protection module exceeds its set value. Detailed information about the active module is available at the <strong>STR_UFRQ</strong> and <strong>STR_FRG</strong> outputs. The shortest operate delay time from the set <strong>Operate Tm Freq</strong> or <strong>Operate Tm df/dt</strong> is dominant regarding the <strong>OPERATE</strong> output. The time characteristic is according to DT. The characteristic that activates the <strong>OPERATE</strong> output can be seen from the <strong>OPR_UFRQ</strong> or <strong>OPR_FRG</strong> output. If the frequency gradient restores before the module operates, the reset timer is activated. If the timer reaches the value set by the <strong>Reset delay Tm df/dt</strong> setting, the operate timer resets and the <strong>STR_FRG</strong> output is deactivated. If the frequency restores before the module operates, the reset timer is activated. If the timer reaches the value set by the <strong>Reset delay Tm Freq</strong> setting, the operate timer resets and the <strong>STR_UFRQ</strong> output is deactivated.</td>
</tr>
</tbody>
</table>
The module calculates the start duration (\( \text{START\_DUR} \)) value which indicates the percentage ratio of the start situation and set operate time (DT). The start duration is available according to the selected value of the Operation mode setting.

**Table 235: Start duration value**

<table>
<thead>
<tr>
<th>Operation mode in use</th>
<th>Available start duration value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Freq&lt;</td>
<td>( \text{ST_DUR_UFRQ} )</td>
</tr>
<tr>
<td>Freq&gt;</td>
<td>( \text{ST_DUR_OFREQ} )</td>
</tr>
<tr>
<td>df/dt</td>
<td>( \text{ST_DUR_FRG} )</td>
</tr>
</tbody>
</table>

The combined start duration \( \text{START\_DUR} \) indicates the maximum percentage ratio of the active protection modes. The values are available via the Monitored data view.

**Blocking logic**

There are three operation modes in the blocking functionality. The operation modes are controlled by the BLOCK input and the global setting “Configuration/System/Blocking mode” which selects the blocking mode. The BLOCK input can be controlled by a binary input, a horizontal communication input or an internal signal of the relay program. The influence of the BLOCK signal activation is preselected with the global setting Blocking mode.

The Blocking mode setting has three blocking methods. In the “Freeze timers” mode, the operate timer is frozen to the prevailing value. In the “Block all” mode, the whole function is blocked and the timers are reset. In the “Block OPERATE output” mode, the function operates normally but the OPERATE output is not activated.

**4.4.1.5 Application**

The frequency protection function uses the positive phase-sequence voltage to measure the frequency reliably and accurately.

The system frequency stability is one of the main principles in the distribution and transmission network maintenance. To protect all frequency-sensitive electrical apparatus in the network, the departure from the allowed band for a safe operation should be inhibited.

The overfrequency protection is applicable in all situations where high levels of the fundamental frequency of a power system voltage must be reliably detected. The high fundamental frequency in a power system indicates an unbalance between production and...
consumption. In this case, the available generation is too large compared to the power
demanded by the load connected to the power grid. This can occur due to a sudden loss of
a significant amount of load or due to failures in the turbine governor system. If the
situation continues and escalates, the power system loses its stability.

The underfrequency is applicable in all situations where a reliable detection of a low
fundamental power system voltage frequency is needed. The low fundamental frequency
in a power system indicates that the generated power is too low to meet the demands of the
load connected to the power grid.

The underfrequency can occur as a result of the overload of generators operating in an
isolated system. It can also occur as a result of a serious fault in the power system due to
the deficit of generation when compared to the load. This can happen due to a fault in the
grid system on the transmission lines that link two parts of the system. As a result, the
system splits into two with one part having the excess load and the other part the
Corresponding deficit.

The frequency gradient is applicable in all the situations where the change of the
fundamental power system voltage frequency should be detected reliably. The frequency
Gradient can be used for both increasing and decreasing the frequencies. This function
provides an output signal suitable for load shedding, generator shedding, generator
boosting, set point change in sub-transmission DC systems and gas turbine startup. The
frequency gradient is often used in combination with a low frequency signal, especially in
smaller power systems where the loss of a large generator requires quick remedial actions
to secure the power system integrity. In such situations, the load shedding actions are
required at a rather high frequency level. However, in combination with a large negative
frequency gradient, the underfrequency protection can be used at a high setting.

4.4.2.2 Function block

![Function block diagram]

4.4.2.3 Functionality

The load shedding and restoration function 81S is capable of performing load shedding based on underfrequency and the rate of change of the frequency. The load that is shed during the frequency disturbance can be restored once the frequency has stabilized to the normal level.

The measured system frequency is compared to the set value to detect the underfrequency condition. The measured rate of change of frequency (df/dt) is compared to the set value to detect a high frequency reduction rate. The combination of the detected underfrequency and the high df/dt is used for the activation of the load shedding. There is a definite time delay between the detection of the underfrequency and high df/dt and the activation of 81S.
This time delay can be set and it is used to prevent unwanted load-shedding actions when the system frequency recovers to the normal level.

Throughout this document, “high df/dt” is used to mean “a high rate of change of the frequency in negative direction.”

Once the frequency has stabilized, 81S can restore the load that is shed during the frequency disturbance. The restoration is possible manually or automatically.

The function contains a blocking functionality. It is possible to block function outputs, timers or the function itself, if desired.

4.4.2.4 Operation principle

The function can be enabled and disabled with the Operation setting. The corresponding parameter values are “On” and “Off”.

The operation of the load shedding and restoration function can be described using a module diagram. All the modules are explained in the next sections.
Underfrequency detection

The underfrequency detection measures the input frequency calculated from the voltage signal. An underfrequency is detected when the measured frequency drops below the set value of the Start Value Freq setting.

The underfrequency detection module includes a timer with the Definite Time (DT) characteristics. Upon detection of underfrequency, operation timer activates the ST_FRQ output. When the underfrequency timer has reached the value set by Operate Tm Freq, the OPR_FRQ output is activated if the underfrequency condition still persists. If the frequency becomes normal before the module operates, the reset timer is activated. If the reset timer reaches the value set by Reset delay time, the timer resets and the ST_FRQ output is deactivated.

df/dt detection

The df/dt detection measures the input frequency calculated from the voltage signal and calculates its gradient. A high df/dt condition is detected by comparing the gradient to the...
**Start value df/dt** setting. The df/dt detection is activated when the frequency gradient decreases at a faster rate than the set value of Start value df/dt.

The df/dt detection module includes a timer with the DT characteristics. Upon detection of df/dt, operation timer activates the ST_FRG output. When the timer has reached the value set by Operate Tm df/dt, the OPR_FRG output is activated if the df/dt condition still persists. If df/dt becomes normal before the module operates, the reset timer is activated. If the reset timer reaches the value of the Reset delay time setting, the timer resets and the ST_FRG output is deactivated.

**Load-shedding control**

The way of load shedding, that is, whether to operate based on underfrequency or high df/dt or both, is defined with the Load shed mode user setting. The valid operation modes for the Load shed mode settings are “Freq<“, “Freq< AND df/dt” and “Freq< OR df/dt”.

Once the selected operation mode conditions are satisfied, the START and OPERATE output signals are activated.

When the START output is active, the percentage of the elapsed delay time can be monitored through START_DUR which is available as monitored data.
**Figure 103:** Load-shedding operation in the “Freq< AND df/dt>” mode when both Freq< and df/dt conditions are satisfied (Rated frequency=50 Hz)
Figure 104: Load-shedding operation in the “Freq< AND df/dt>” mode when only the df/dt condition is satisfied (Rated frequency=50 Hz)

Restore detection

If after the activation of the OPERATE input the frequency recovers to a level above the Restore start Val setting, the RESTORE signal output is activated. The RESTORE output remains active for a 100 ms. The Restore mode setting is used to select the restoring mode to be “Disabled”, “Auto” or “Manual”.

<table>
<thead>
<tr>
<th>Restoring mode</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Disabled</td>
<td>Load restoration is disabled.</td>
</tr>
<tr>
<td>Auto</td>
<td>In the “Auto” mode, input frequency is continuously compared to the Restore start Val setting. The restore detection module includes a timer with the DT characteristics. Upon detection of restoring, the operation timer activates the ST_REST output. When the timer has reached the value of the Restore delay time setting, the RESTORE output is activated if the restoring condition still persists. If the frequency drops below the Restore start Val before the RESTORE output is activated, the reset timer is activated. If the reset timer reaches the value of the Reset delay time setting, the timer resets and the ST_REST start output is deactivated.</td>
</tr>
</tbody>
</table>
A condition can arise where the restoring operation needs to be canceled. Activating the BLK_REST input for the “Auto” or “Manual” modes cancels the restoring operation. In the “Manual” restoring mode, the cancellation happens even if MAN_RESTORE is present.

Once the RESTORE output command is cancelled, the reactivation of RESTORE is possible only after the reactivation of the OPERATE output, that is, when the next load-shedding operation is detected.

### Blocking logic

There are three operation modes in the blocking functionality. The operation modes are controlled by the BLOCK input and the Configuration > System > Blocking mode global setting that selects the blocking mode. The BLOCK input can be controlled with a binary input, a horizontal communication input or an internal signal of the relay program. The influence of the BLOCK input signal activation is preselected with the Blocking mode global setting.

The Blocking mode setting has three blocking methods. In the “Freeze timers” mode, the operate timer is frozen to the prevailing value. In the “Block all” mode, the whole function is blocked and the timers are reset. In the “Block OPERATE output” mode, the function operates normally but the OPERATE, OPR_FRQ and OPR_FRG outputs are not activated.

### Application

An AC power system operates at a defined rated frequency. The nominal frequency in most systems in the world is 50 Hz or 60 Hz. The system operation is such that the operating frequency remains approximately at the nominal frequency value by a small margin. The safe margin of operation is usually less than ±0.5 Hz. The system frequency stability is one of the main concerns in the transmission and distribution network operation and control. To protect the frequency-sensitive electrical equipment in the network, departure from the allowed band for safe operation should be inhibited.

Any increase in the connected load requires an increase in the real power generation to maintain the system frequency. Frequency variations form whenever there are system conditions that result in an unbalance between the generation and load. The rate of change of the frequency represents the magnitude of the difference between the load and generation. A reduction in frequency and a negative rate of change of the frequency are observed when the load is greater than the generation, and an increase in the frequency along with a positive rate of change of the frequency are observed if the generation is greater than the load. The rate of change of the frequency is used for a faster decision of load shedding. In an underfrequency situation, the load shedding trips out the unimportant
loads to stabilize the network. Thus, loads are normally prioritized so that the less important loads are shed before the important loads.

During the operation of some of the protective schemes or other system emergencies, the power system is divided into small islands. There is always a load - generation imbalance in such islands that leads to a deviation in the operating frequency from the nominal frequency. This off-nominal frequency operation is harmful to power system components like turbines and motors. Therefore, such situation must be prevented from continuing. The frequency-based load-shedding scheme should be applied to restore the operation of the system to normal frequency. This is achieved by quickly creating the load - generation balance by disconnecting the load.

As the formation of the system islands is not always predefined, several load-shedding relays are required to be deployed at various places near the load centers. A quick shedding of a large amount of load from one place can cause a significant disturbance in the system. The load-shedding scheme can be made most effective if the shedding of load feeders is distributed and discrete, that is, the loads are shed at various locations and in distinct steps until the system frequency reaches the acceptable limits.

Due to the action of load-shedding schemes, the system recovers from the disturbance and the operating frequency value recovers towards the nominal frequency. The load that was shed during the disturbance can be restored. The load-restoring operation should be done stepwise in such a way that it does not lead the system back to the emergency condition. This is done through an operator intervention or in case of remote location through an automatic load restoration function. The load restoration function also detects the system frequency and restores the load if the system frequency remains above the value of the set restoration frequency for a predefined duration.
The decision on the amount of load that is required to be shed is taken through the measurement of frequency and the rate of change of frequency (df/dt). At a single location, many steps of load shedding can be defined based on different criteria of the frequency and df/dt. Typically, the load shedding is performed in six or four steps with each shedding increasing the portion of load from five to twenty-five percent of full load within a few seconds. After every shedding, the system frequency is read back and further shedding actions are taken only if necessary. In order to take the effect of any transient, a sufficient time delay should be set.

The value of the setting has to be well below the lowest occurring normal frequency and well above the lowest acceptable frequency of the system. The setting level, the number of steps and the distance between two steps (in time or in frequency) depend on the characteristics of the power system under consideration. The size of the largest loss of generation compared to the size of the power system is a critical parameter. In large systems, the load shedding can be set at a high frequency level and the time delay is normally not critical. In small systems, the frequency start level has to be set at a low value and the time delay must be short.

If a moderate system operates at 50 Hz, an underfrequency should be set for different steps from 49.2 Hz to 47.5 Hz in steps of 0.3 – 0.4 Hz. The operating time for the underfrequency can be set from a few seconds to a few fractions of a second stepwise from a higher frequency value to a lower frequency value.

</tr>
</tbody>
</table>

The rate of change of frequency function is not instantaneous since the function needs time to supply a stable value. It is recommended to have a time delay long enough to take care of the signal noise.

Small industrial systems can experience the rate of change of frequency as large as 5 Hz/s due to a single event. Even large power systems can form small islands with a large imbalance between the load and generation when severe faults or combinations of faults are cleared. Up to 3 Hz/s has been experienced when a small island becomes isolated from a large system. For normal severe disturbances in large power systems, the rate of change of the frequency is much less, often just a fraction of 1.0 Hz/s.

Similarly, the setting for df/dt can be from 0.1 Hz/s to 1.2 Hz/s in steps of 0.1 Hz/s to 0.3 Hz/s for large distributed power networks, with the operating time varying from a few seconds to a few fractions of a second. Here, the operating time should be kept in minimum for the higher df/dt setting.

</tr>
</tbody>
</table>

Once the frequency has stabilized, the shed load can be restored. The restoring operation should be done stepwise, taking care that it does not lead the system back to the emergency condition.

##### 4.5.1.2 Function block

![Function block diagram](image)

**Figure 106:** Function block

##### 4.5.1.3 Functionality

The breaker failure function 50BFT is activated by trip commands from other protection functions. The commands are either internal commands to the terminal or external commands through binary inputs. The pickup or start input command can be single phase or common for all three phases depending on the choice whether single phase or three phase function is chosen. 50BFT includes a single or all three phase conditional or unconditional re-trip function, and also back-up trip function.

50BFT uses the same levels of current detection for both re-trip and back-up trip. The operating values of the current measuring elements can be set within a predefined setting range. The function has two independent timers for trip purposes: a re-trip timer for the repeated tripping of its own breaker and a back-up timer for the trip logic operation for upstream breakers. A minimum trip pulse length can be set independently for the trip output.

The function contains a blocking functionality. It is possible to block the function outputs, if desired.

##### 4.5.1.4 Operation principle

The function can be enabled and disabled with the *Operation* setting. The corresponding parameter values are Enable and Disable.

The operation of breaker failure protection can be described by using a module diagram in the figure below, typically for Phase A, when single phase operation mode is selected. All
the blocks in the diagram are explained in the next sections. Also further information on retrip and back-up trip logics is given in sub-module diagrams.

Figure 107: Functional module diagram, typical for Phase A when Single Phase Operation mode is selected

Level detector Current Value

In the above figure, the measured phase currents are compared phase-wise with the set Current value. If the measured value exceeds the set Current value, the level detector reports the exceeding of the value to the retrip and back-up trip logics. The parameter should be set low enough so that situations with small fault current or high load current can be detected. The setting can be chosen in accordance with the most sensitive protection function to start the breaker failure protection.

When mode is selected for 3phase operation, the same setting Current Value is also used to initiate 3 pole breaker fail trip initiation whenever the input START gets an initiation gets energized. In this case the highest of the three phase currents are used to compare against the set Current Value setting (See Figure below).
Level detector **Current Value Res**

When operation mode is selected as three phase and when the input START is energized, the comparator, comparing the measured ground current or residual current with the set **Current value Res** is effective. When three phase mode is chosen, the input POSCLOSE is internally derived as AND combination of POSCLOSE_A, POSCLOSE_B and POSCLOSE_C inputs to the logic. When three pole tripping device is involved, the breaker close position can be looped to all the three inputs.

In three phase operation mode, if the measured ground current value exceeds the set **Current value Res**, the level detector reports the exceeding of the value to the back-up trip logic. In high impedance grounded systems, the ground current at phase to ground faults are normally much smaller than the short circuit currents. To detect a breaker failure at single-phase ground faults in these systems, it is necessary to measure the ground current separately. In effectively grounded systems, also the setting of the ground-fault current protection can be chosen at a relatively low current level. The **CB failure trip mode** is set “1 out of 4”. The current setting should be chosen in accordance with the setting of the sensitive ground-fault protection.

**Retrip logic**

The operation of the retrip logic can be described by using a module diagram, for three phase operation:
Protection functions

Figure 109: Retrip logic internal design

The retrip function operates with or without a current check selected with the CB fail retrip mode setting. In “Current check” mode, the retrip is only performed if the current through the circuit breaker exceeds the Current value level. In “Without check” mode, the retrip is done without checking the phase currents.

The CB failure mode setting is used to select the mode the breaker fault is detected with. In “Current” mode, the detection is based on the current level exceeding. In “Breaker status” mode, the detection is based on the closed position of the circuit breaker after a trip signal is issued, that is, after a long duration of the trip signal. In “Both” mode, the detection is based either on the exceeding of Current value level or on the long duration of the trip signal. When external information of a circuit breaker fault is connected to the active CB_FAULT input, the retrip function is not allowed to trip. The blocking is used to disable the whole function.

Back-up trip logic

The operation of the back-up trip logic can be described by using a module diagram when three phase operation mode is selected:
The current detection characteristics can be selected with the CB failure trip mode setting in three following options:

- “1 out of 3” in which detecting opening failure (high current) in one phase only is sufficient
- “1 out of 4” in which detecting opening failure (high current) or high ground current in one phase only is sufficient
- “2 out of 4” in which at least two high currents (phase current and/or ground current) are required for breaker failure detection.

In most applications, “1 out of 3” is sufficient. In the “Breaker status” mode, the back-up trip is done when the status inputs indicate that the circuit breaker is in closed state.

The setting CB failure mode is used to select the mode the breaker fault is detected with. In “Current” mode, the detection is based on the current level exceeding. In “Breaker status” mode, the detection is based on the closed position of the circuit breaker after a trip signal is issued, that is, after a long duration of the trip signal. In "Both" mode, the detection is based either on the exceeding of the Current value Res level, depending on the current detection mode, or on the long duration of the trip signal. When external information on a circuit breaker fault is connected to the active CB_FAULT input, the back-up trip function is issued to the upstream breaker without delay. The blocking is used for disabling the whole function.

**Timer 1**

Once activated, the timer runs until the set Retrip time value has elapsed. The time characteristic is according to DT. When the operation timer has reached the maximum time value, the TRRET output is activated. A typical setting is 0 - 50 ms.
Timer 2

Once activated, the timer runs until the set CB failure delay value is elapsed. The time characteristic is according to DT. When the operation timer has reached the set maximum time value CB failure delay, the TRBU output is activated. The value of this setting is made as low as possible at the same time as any unwanted operation is avoided. A typical setting is 90 - 150 ms which is also dependent on the retrip timer.

The minimum time delay for the retrip can be estimated as:

\[ CB\text{failuredelay} \geq Retriptime + t_{cbopen} + t_{BFP\_reset} + t_{margin} \]

- \( t_{cbopen} \) is the maximum opening time for the circuit breaker
- \( t_{BFP\_reset} \) is the maximum time for the breaker failure protection to detect the correct breaker function (the current criteria reset)
- \( t_{margin} \) is the safety margin

It is often required that the total fault clearance time is less than the given critical time. This time is often dependent on the ability to maintain transient stability in case of a fault close to a power plant.

![Time line of breaker failure protection](image)

**Figure 111:** Time line of breaker failure protection

Timer 3

This module is activated by the CB_FAULT signal. Once activated, the timer runs until the set CB fault delay value is elapsed. The time characteristic is according to DT. When the operation timer has reached the maximum time value, the CB_FAULT_AL output is activated. After the set time an alarm is given so that actions can be done to repair the circuit breaker. A typical value is 5 s.
4.5.1.5 Application

The n-1 criterion is often used in the design of a fault clearance system. This means that the fault is cleared even if some component in the fault clearance system is faulty. A circuit breaker is a necessary component in the fault clearance system. For practical and economical reasons, it is not feasible to duplicate the circuit breaker for the protected component, but breaker failure protection is used instead.

The breaker failure function issues a back-up trip command to adjacent circuit breakers in case the original circuit breaker fails to trip for the protected component. The detection of a failure to break the current through the breaker is made by measuring the current or by detecting the remaining trip signal (unconditional).

50BFT can also retrip. This means that a second trip signal is sent to the protected circuit breaker. The retrip function is used to increase the operational reliability of the breaker. The function can also be used to avoid back-up tripping of several breakers in case mistakes occur during relay maintenance and tests.

50BFT is initiated by operating different protection functions or digital logics inside the relay. It is also possible to initiate the function externally through a binary input.

50BFT can be blocked by using an internally assigned signal or an external signal from a binary input. This signal blocks the function of the breaker failure protection even when the timers have started or the timers are reset.

The retrip timer is initiated after the pickup input is set to true. When the pre-defined time setting is exceeded, 50BFT issues the retrip and sends a trip command, for example, to the circuit breaker's second trip coil. Both a retrip with current check and an unconditional retrip are available. When a retrip with current check is chosen, the retrip is performed only if there is a current flow through the circuit breaker.

The backup trip timer is also initiated at the same time as the retrip timer. If 50BFT detects a failure in tripping the fault within the set backup delay time, which is longer than the retrip time, it sends a backup trip signal to the chosen backup breakers. The circuit breakers are normally upstream breakers which feed fault current to a faulty feeder.

The backup trip always includes a current check criterion. This means that the criterion for a breaker failure is that there is a current flow through the circuit breaker after the set backup delay time.

**Figure 113**: Function block

4.5.2.3 Functionality

The breaker close failure function 50BFC is activated by close commands from either internal auto reclose commands or external commands through START inputs. The pickup or start input command can be single phase or common for all three phases depending on the choice whether single phase or three phase breaker operation mode is chosen. 50BFC includes a single or all three phase unconditional re-close function.

The function has a timer for attempting automatically a re-close timer for the repeated closing of the intended breaker. A minimum close pulse length can be set independently for the output.

The function contains a blocking functionality. It is possible to block the function outputs, if desired.

4.5.2.4 Operation principle

The function can be enabled and disabled with the *Operation* setting. The corresponding parameter values are Enable and Disable.

The operation of breaker close failure protection can be described by using a module diagram, as shown in the top portion of the logic diagram shown in the figure next page. The signal inputs POS_CLOSE_A, START_A and BLOCK inputs are processed in the Start logic block. Any attempt to close the A pole of the breaker, as decided by the input START_A input going high generates command to try reclosing the breaker after the set close delay time, for a duration of close pulse time, set in the unit. Alarm generation on unsuccessful attempt can be done external to this logic in the unit.
The following figure is applicable when 3 phase operation mode is selected in the unit. The signal input POSCLOSE is typically the status input of a three pole breaker / recloser. In case there are separate pole operating mechanisms, the input is OR combination of all three phase inputs either through parallel connection of 52a inputs wired to a binary input or through a logic.
Figure 115: Functional module diagram, for three phase breaker close failure function when three phase operation mode is selected.

4.5.3.2 Function block symbol

![Function block symbol](image)

**Figure 116:** Function block symbol

4.5.3.3 Functionality

A small percentage of ground faults have a very large impedance. They are comparable to load impedance and consequently have very little fault current. These high impedance faults do not pose imminent danger to power system equipment. However, they are a substantial threat to humans and properties; people can touch or get close to conductors carrying large amounts of energy.

The high impedance fault-detector function HIZ also contains a blocking functionality. It is possible to block function outputs, if desired.

4.5.3.4 Principle of operation

The function can be enabled and disabled with the *Operation* setting. The corresponding parameter values are Enable and Disable.

HIZ uses a multi-algorithm approach. Each algorithm uses various features of ground currents to detect a high impedance fault.

![Electrical power system equipped with HIZ](image)

**Figure 117:** Electrical power system equipped with HIZ

Power system signals are acquired, filtered, and then processed by individual high impedance fault detection algorithm. The results of these individual algorithms are further processed by decision logic to provide the detection decision. The decision logic can be modified depending on the application requirement.
Figure 118: Block diagram of HIZ

HIZ is based on algorithms that use ground current signatures which are considered non stationary, temporally volatile, and of various burst duration. All harmonic and non-harmonic components within the available data window can play a vital role in the high impedance fault detection. A major challenge is to develop a data model that acknowledges that high impedance faults could take place at any time within the observation window of the signal and could be delayed randomly and attenuated substantially. The model is motivated by extensive research, actual experimental observations in the laboratory, field testing, and what traditionally represents an accurate depiction of a non stationary signal with a time dependent spectrum.

Figure 119: Validation of HIZ on gravel
Figure 120: Validation of HIZ on concrete
Figure 121: Validation of HIZ on sand
Figure 122: Validation of HIZ on grass
4.5.3.5 Application

Electric power lines experience faults for many reasons. In most cases, electrical faults manifest in mechanical damage, which must be repaired before returning the line to service.

Most of these faults are ground faults. Conventional protection systems based on overcurrent, impedance, or other principles are suitable for detecting relatively low impedance faults, which have a relatively large fault current.

However, a small percentage of the ground faults have a very large impedance. They are comparable to load impedance and consequently have very little fault current. These high impedance faults do not pose imminent danger to power system equipment. However, they are a considerable threat to people and property. The IEEE Power System Relay Committee working group on High Impedance Fault Detection Technology defines High Impedance Faults as those that 'do not produce enough fault current to be detectable by conventional overcurrent relays or fuses'.

High impedance fault (HIZ) detection requires a different approach than that for conventional low impedance faults. Reliable detection of HIZ provides safety to humans and animals. HIZ detection can also prevent fire and minimize property damage. ABB has developed innovative technology for high impedance fault detection with over seven years of research resulting in many successful field tests.

- I_C
```

*Figure 123: Function block*

4.5.4.3 Functionality

The fault locator function performs the estimation of apparent distance to fault and fault resistance. The calculation is performed by comparing the pre-fault current and voltage phasor by fault current and voltage phasor along with line parameters.

The fault loop is determined and the respective voltage and current phasor are selected for the fault location algorithm. The pre fault current and voltage phasor are used to calculate the pre fault load impedance and fault current and voltage phasor are used to calculate the apparent impedance during the fault. The load impedance, apparent impedance and line parameters are used to estimate the fault resistance and distance to fault.

4.5.4.4 Operation principle

The *Operation* setting is used to enable or disable the function. When selected “On” the function is enabled and respectively “Off” means function is disabled.

The operation of FLO can be described by using a module diagram (see Figure 124). All the modules in the diagram are explained in the next sections.
Buffering logic

This module buffers the three phase voltage and current phasor input values (DFT values of \(V_A, V_B, V_C, I_A, I_B, I_C\)). Once the phase current magnitude is more than the \textit{Phase Level} setting the pre-fault buffer will freeze and updating of fault buffer will be started. The fault buffer will freeze once the buffer is updated fully. The fault location algorithm will be started only if Relay Trip signal is detected.

Fault loop determination

Any fault can be categorized as either a phase to phase fault or a phase to ground fault.

The fault loop determination algorithm determines whether the fault is a phase to ground fault or phase to phase fault by comparing the phase currents with zero sequence current.

This module determines the fault loop from pre-fault and fault phasor stored in the respective buffers. The fault typing is the procedure to identify the type of fault and therefore the respective voltage and current phasor can be selected from the pre-fault and fault buffers, for the fault location algorithm.

Once the fault has been classified as either a phase to ground or phase to phase fault, then the specific fault loop is determined by comparing all phase currents with the setting \textit{Phase Level}. Fault loop determination is done in accordance with Table 267.
Once the specific fault type is determined, the respective fault loop voltage and current phasor are taken for fault location algorithm.

If the fault is any single phase to ground fault, then the respective phase current should be ground compensated.

The procedure for the ground compensation is given below,

For ground fault cases, the current measured at the relay is ground compensated by employing the following formula:

\[
I_{ry}^* = I_{ry} + k \cdot I_0 \cdot (ZL_{zero} - ZL_{pos}) / ZL_{pos}
\]

where

\[
I_0 = (I_A + I_B + I_C) / 3
\]

\[
k = 1.0 \text{ (scaling factor)}
\]

\[
ZL_{pos} \text{ and } ZL_{zero} \text{ refer to positive and zero sequence line impedances.}
\]

\[
ZL_{pos} = RL_{pos} + j \cdot XL_{pos}
\]

\[
ZL_{zero} = RL_{zero} + j \cdot XL_{zero}
\]

\[
RL_{pos} = \text{PosSeqR} \cdot \text{LinLen}
\]

\[
XL_{pos} = \text{PosSeqX} \cdot \text{LinLen}
\]

\[
RL_{zero} = \text{ZeroSegR} \cdot \text{LinLen}
\]

\[
XL_{zero} = \text{ZeroSegX} \cdot \text{LinLen}
\]

\[
I_{ry}^* = \text{Ground compensated phase current}
\]

\[
I_{ry} = \text{Non-compensated phase current}
\]
**Protection functions**

*R1* is positive sequence line resistance in ohm/ (miles or kms) and is provided as a setting.

*X1* is positive sequence line reactance in ohm/ (miles or kms) and is provided as a setting.

*R0* is zero sequence line resistance in ohm/ (miles or kms) and is provided as a setting.

*X0* is zero sequence line reactance in ohm/ (miles or kms) and is provided as a setting.

*Line Length* is the length of the line in the units of kilometers (Km) or miles and is provided as a setting.

If *R1, X1, R0, X0* are given in ohm/mile then the length of the line *Line Length* should be given in the unit of miles.

If *R1, X1, R0, X0* are given in ohm/Km then the length of the line *Line Length* should be given in the unit of Km’s.

Table 268 describes what will be the voltage phasor and current phasor under different fault types.

**Fault location**

This module calculates the distance to fault and fault resistance from the voltage phasor and current phasor selected based on type of the fault (see Table 268).

The algorithm uses the fundamental frequency phasor voltages and currents measured at the relay terminal before and during the fault.

The algorithm basically is an iterative technique, performs a comparison of the pre fault load impedance and apparent impedance during the fault, to estimate the distance to fault.

Estimated values of fault resistance, pre fault load impedance and line impedance are then modified using the correction factors. And the corrected values are used to estimate the final FLT_DIST and FLT_R.

During the auto-re-closure sequences the fault location is done with initial fault conditions.
4.5.4.5 Application

Electrical power system has grown rapidly over the last few decades. This resulted in a large increase of the number of lines in operation and their total length. These lines experience faults which are caused by storms, lightning, snow, freezing rain, insulation breakdown and short circuits caused by birds and other external objects. In most cases, electrical faults manifest in mechanical damage, which must be repaired before returning the line to service. The restoration can be expedited if the location of the fault is either known or can be expedited with reasonable accuracy.

Fault locators provide estimate for both sustained and transient faults. Generally transient faults cause minor damage that is not easily visible on inspection. Fault locators help identify those locations for early repairs to prevent recurrence and consequent major damage.

The fault location algorithm is most applicable for radial feeder. The algorithm is based on the system model shown in Figure 125. The algorithm was designed to be used on a homogeneous radial distribution line. Therefore the unit is not intended to be used on a distribution line with many different types of conductors because the algorithm will not be as accurate. Fault locator algorithm may not be accurate for switch on to fault condition.

4.5.5 Directional positive sequence power protection 32P

The directional positive sequence power protection (32P) function detects power direction for phase directional power. Release signal is given if the angle difference polarizing and operating quantity is in predefined direction (forward or reverse direction). The release signal is given with definite time delay.

4.5.5.1 Identification

4.5.5.2 Function block

Figure 126: Function block

4.5.5.3 Functionality

The directional positive sequence power protection (32P) function is used to detect positive sequence power direction. The output of the function is used for blocking or releasing other functions in protection scheme.

This function contains a blocking functionality which blocks function output and resets the timer.

4.5.5.4 Operation principle

The Operation setting is used to enable or disable the function. When selected “On” the function is enabled and respectively “Off” means function is disabled.

The operation of 32P can be described by using a module diagram (see Figure 127). All the modules in the diagram are explained in the next sections.
The Directional detector module compares the angle of positive sequence current ($I_1$) to the angle of positive sequence voltage ($V_1$). Using the positive sequence voltage angle as the reference the positive sequence current angle is compared to the Characteristic angle setting. If the angular difference is within the operating sector selected by the Directional mode setting, then enable signal is sent to the Timer.

The operating sector is defined by the setting Min forward angle, Max forward angle, Min reverse angle, and Max reverse angle (see Figure 128). The user selectable options for Directional mode settings are “Forward” and “Reverse”.

The sector limits are always given as positive degree values.

The Characteristic angle is also known as Relay Characteristic Angle (RCA), Relay Base Angle or Maximum Torque Line.
Low level blocking

For reliable operation, signals levels should be greater than minimum level. If they are not greater than minimum level, Timer is blocked. If the amplitude of the positive sequence current amplitude is greater than Min Trip Current value and positive sequence voltage amplitude is greater than Min operate voltage value then enable signal is sent to the Timer.

Timer

Once activated the internal operate timer is started. The timer characteristic is according to Definite Time (DT). When the Timer has reached the value of Release delay time, the RELEASE output is activated. If a drop-off situation happens, that is if operating current moves outside operating sector or signal amplitudes becomes below the minimum level before Release delay time is exceeded, the timer reset state is activated. If drop off continues for more than Reset delay time the Timer is deactivated.

Blocking logic

The binary input BLOCK can be used to block the function. The activation of the BLOCK input deactivates RELEASE output and resets the Timer.

4.5.5.5 Application

The 32P function improves the possibility to obtain selective function of the overcurrent protection in meshed networks. The 32P function is used to block or release other overcurrent protection functions.

### 4.5.6 Directional negative/zero sequence power protection 32N

Directional negative/zero sequence power protection (32N) is used to detect the direction of negative sequence power or residual power.

Release signal is given if the angle difference between polarizing and operating quantity is in predefined direction (forward or reverse direction). The release signal is given with a definite time delay.

#### 4.5.6.1 Identification

<td>Q=&gt;-&gt;</td>
<td>32N</td>
</tr>
</tbody>
</table>
4.5.6.2 Function block

Figure 129: Function block

4.5.6.3 Functionality

Directional negative/zero sequence power protection (32N) is used to detect negative or residual power direction. The output of the function is used for blocking or releasing other functions in protection scheme.

In negative sequence voltage selection, if the angle difference between negative sequence voltage and negative sequence current is in predefined direction (either in forward or reverse direction), 32N gives release signal after a definite time delay.

In residual voltage selection, if the angle difference between residual voltage and residual current is in predefined direction (either in forward or reverse direction), 32N gives release signal after a definite time delay.

This function contains a blocking functionality which blocks the function output and resets the timer.

4.5.6.4 Operation principle

The Operation setting is used to enable or disable the function. When selected “On” the function is enabled and respectively “Off” means function is disabled.

The operation of 32N can be described by using a module diagram (see Figure 130). All the modules in the diagram are explained in the next sections.
Directional detector

When “Neg. seq. volt.” selection is made using Pol signal Sel, the directional detector module compares angle of negative sequence current ($I_2$) to the negative sequence voltage ($-V_2$). Using the negative sequence voltage angle as the reference the negative sequence current angle is compared to the Characteristic angle. If the angle difference is within the operating sector selected by Direction mode setting then enable signal is sent to the Timer.

The value of Characteristic angle should be chosen in such way that all the faults in the operating direction are seen in the operating zone and all the faults in the opposite direction are seen in the backward zone.

The operating sector is defined by the settings Max forward angle, Max reverse angle, Min forward angle and Min reverse angle (see Figure 131). User selectable options for Directional mode are “Forward” and “Reverse”.

**Figure 130:** Functional module diagram
The Characteristic angle is also known as Relay Characteristic Angle (RCA), Relay Base Angle or Maximum Torque Line.

![Diagram showing configurable directional setting](image)

**Figure 131:** Configurable directional setting when “Neg. seq. volt.” selection is made using Pol signal Sel

When “Measured \(V_G\)” or “Calculated \(V_N\)” voltage selection is made using Pol signal Sel setting, the Directional detector module compares the angle of the residual current to the residual voltage. Using the residual voltage as reference the residual current angle is compared to the Characteristic angle setting. If the angle difference is within the operating sector selected by Directional mode setting, then enable signal is sent to the Timer.

The “Measured IG” or “Calculated IN” (residual current) can be selected using \(I_0\) signal Sel setting.

The “Measured VG”, “Calculated VN” (residual voltage) can be selected using Pol signal Sel setting.

The polarizing quantity (residual voltage) is inverted because of switched voltage measurement cables, the correction can be done by setting the Pol reversal setting to “True” which rotates polarizing quantity by 180 degrees.

The operating sector is defined by the settings Max forward angle, Max reverse angle, Min forward angle, and Min reverse angle (see Figure 131). User selectable options for Directional mode are “Forward” and “Reverse”.
The directional characteristic for measured or calculated residual power is same.

![Diagram showing configurable directional setting for measured or calculated residual power]

**Figure 132:** Configurable directional setting for “Measured $V_G$” or “Calculated $V_N$” (residual voltage) using Pol signal Sel setting

The Characteristic angle setting is done based on method of grounding employed in the network. For example, in case of isolated network, the Characteristic angle is set equal to -90°. In case of compensated network, the Characteristic angle is set equal to 0° and 60° for solidly grounded systems. In general, Characteristic angle is selected so that it matches close to the expected fault angle value, which results into maximum sensitivity. The Characteristic angle can be set anywhere between -179° to +180°. Figure 133 and Figure 134 show examples of the operating area with RCA set to +60° and -90°, respectively.
Section 4
Protection functions

**Figure 133:** Configurable directional characteristics (RCA =+60°) for a solidly earthed network

**Figure 134:** Configurable directional characteristics (RCA =-90°) for an isolated network

The Characteristic angle should be set to a positive value if the operating signal, IG or IN lags the polarizing quantity –VG or –VN, respectively, and a negative value if operating signal IG or IN leads the polarizing quantity –VG or –VN, respectively.
The Characteristic angle setting is adjusted to the operation according to the method of neutral point earthing so that in an isolated network the Characteristic angle = -90° and in a compensated network = 0°. In addition, the Characteristic angle can be changed via the control signal RCA_CTL, in which case the alternatives are -90° and 0°. The operation of the RCA_CTL depends on the Characteristic angle setting.

The Peterson coil or the earthing resistor may be temporarily out of operation. To keep the protection scheme selective, it is necessary to update the Characteristic angle accordingly. This is done with an auxiliary input in the relay which receives a signal from an auxiliary switch of the disconnector of the Peterson coil in compensated networks or of the earthing resistor in earthed network as a result the Characteristic angle is set automatically to suit the earthing method. The table below shows the Characteristic angle control for RCA_CTL condition.

**Table 279: Recommended Characteristic angle setting for different network**

<td>Characteristic angle = -90°</td>
</tr>
</tbody>
</table>

**Low level blocking**

For reliable operation, signals levels should be greater than minimum level. If they are not greater than minimum level, Timer is blocked.

In “Neg. seq. volt.” polarization selection using Pol signal Sel, if the amplitude of the negative sequence current is greater than Min operate current value and negative sequence voltage amplitude is greater than Min operate voltage value then enable signal is sent to the Timer.

In “Measured VG” or “Calculated VN” polarization selection using Pol signal Sel, if the amplitude of the residual current is greater than the Min operate current value and residual voltage amplitude is greater than the Min operate voltage value then enable signal is sent to the Timer.

**Timer**

Once activated the internal operate timer is started. The timer characteristic is according to Definite Time (DT). When the Timer has reached the value of Release delay time, the RELEASE output is activated. If a drop-off situation happens, that is, if operating current moves out of the operating sector or signal amplitudes become below the minimum levels, before the Release delay time is exceeded, the timer reset state is activated. If drop off continues for more than Reset delay time the Timer is deactivated.
Blocking logic

The binary input BLOCK can be used to block the function. The activation of the BLOCK input deactivates RELEASE output and resets the Timer.

4.5.6.5 Application

The directional negative/zero sequence power protection (32N) function improves the possibility to obtain selective function of the over-current protection in meshed networks. The 32N function is used to block or release other over current protection function.

5.1.3  
Functionality

The circuit breaker control function 52 is intended for circuit breaker control and status information purposes. It supports both conventional three phase control and single phase...
Section 5  
Control functions

control. This function executes commands and evaluates block conditions and different time supervision conditions. The function performs an execution command only if all conditions indicate that a switch operation is allowed. If erroneous conditions occur, the function indicates an appropriate cause value. The function is designed according to the IEC 61850-7-4 standard with logical nodes CILO, CSWI and XCBR.

The circuit breaker control function has an operation counter for closing and opening cycles. The operator can read and write the counter value remotely from an operator place or via LHMI.

5.1.4 Operation principle

Status indication and validity check

The object state is defined by digital inputs OPENPOS_x and CLOSEPOS_x for each phase which are also available as outputs OPENPOS_x and CLOSEPOS_x together with the OKPOS_x information. The debouncing and short disturbances in an input are eliminated by filtering. The binary input filtering time can be adjusted separately for each digital input used by the function block. The validity of the digital inputs that indicate the object state is used as additional information in indications and event logging. The reporting of faulty or intermediate position circuit breaker contacts occurs after the Event delay setting, assuming that the circuit breaker is still in a corresponding state.

Blocking

52 has a blocking functionality to prevent human errors that can cause serious injuries for the operator and damages for the system components.

The basic principle for all blocking signals is that they affect the commands of other clients: the operator place and protection and autoreclose functions, for example. The blocking principles are the following:

- Enabling the open command: the function is used to block the operation of the open command. Note that this block signal also affects the OPEN input of immediate command.
- Enabling the close command: the function is used to block the operation of the close command. Note that this block signal also affects the CLOSE input of immediate command.

The ITL_BYPASS_PH_x input is used if the interlocking functionality needs to be bypassed. When INT_BYPASS is TRUE, the circuit breaker control for the respective phase is made possible by discarding the ENA_OPEN_PH_x and ENA_CLOSE_PH_x input states. However, the BLK_OPEN_PH_x and BLK_CLOSE_PH_x input signals are
not bypassed with the interlocking bypass functionality since they always have higher priority.

**Open and close operations**

The corresponding open and close operations are available via communication, binary inputs or LHMI commands. As a prerequisite for control commands, there are enable and block functionalities for both the close and open commands. If the control command is executed against the blocking, or if the enabling of the corresponding command is not valid, SCBXCBR generates an error message.

**Open and close pulse widths**

The pulse width type can be defined with the *Adaptive pulse* setting. The function provides two modes to characterize the opening and closing pulse widths. When the *Adaptive pulse* is set to TRUE, it causes a variable pulse width, which means that the output pulse is deactivated when the object state shows that the circuit breaker has entered the correct state. When the *Adaptive pulse* is set to FALSE, the function always uses the maximum pulse width, defined by the user-configurable *Pulse length* setting. The *Pulse length* setting is the same for both the opening and closing commands. When the circuit breaker already is in the right position, the maximum pulse length is given. Note that the *Pulse length* setting does not affect the length of the trip pulse.

**Control methods**

The command execution mode can be set with the *Control model* setting. The alternatives for command execution are direct control and secured object control, which can be used to secure controlling.

The secured object control SBO is an important feature of the communication protocols that support horizontal communication, because the command reservation and interlocking signals can be transferred with a bus. All secured control operations require two-step commands: a selection step and an execution step. The secured object control is responsible for the following tasks:

- Command authority: ensures that the command source is authorized to operate the object
- Mutual exclusion: ensures that only one command source at a time can control the object
- Interlocking: allows only safe commands
- Execution: supervises the command execution
- Command cancelling: cancels the controlling of a selected object.

In direct operate, a single message is used to initiate the control action of a physical device. The direct operate method uses less communication network capacity and bandwidth than the SBO method, because the procedure needs fewer messages for accurate operation.
5.1.5 Application

In the field of distribution and sub-transmission automation, reliable control and status indication of primary switching components both locally and remotely is in a significant role. They are needed especially in modern remotely controlled substations.

Control and status indication facilities are implemented in the same package with 52. When primary components are controlled in the energizing phase, for example, the user must ensure that the control commands are executed in a correct sequence. This can be achieved, for example, with interlocking based on the status indication of the related primary components. An example of how the interlocking on substation level can be applied by using the IEC61850 GOOSE messages between feeders is as follows:
Figure 137: Status indication based interlocking via GOOSE messaging

5.2 Autoreclosing 79

The RER620 single-phase tripping and reclosing option is advantageous for use on many electric utility distribution systems, including rural, residential and some commercial
loads. It supports both conventional three phase auto-reclosing and single phase auto-reclosing.

It provides a control capability function of the recloser to trip and/or lockout whenever there is a fault on one-phase, two-phases or three-phases. This feature allows an electric utility to prevent unnecessary three-phase interruptions and outages of their distribution network where a majority of outages can be attributed to single-phase transient type faults thereby improving the overall power system reliability and quantity of power delivered to customers on the distribution feeder.

The operation of the autoreclosing function can be described by using a module diagram.

**Figure 138: Conceptual auto-reclosing function diagram**

The full Autorecloser functionality consists of 3 sections or parts.

The first part of the function consists of SDAIGGIO function blocks determines which phase(s), if any, are to be tripped. This determination is based on the condition of each phase (whether tripped, only picked up or already open).

The second part of the function SDARREC block invokes the core autorecloser function, which determines whether / when to reclose / lockout etc.

The third part of the function consist of SDAOGGIO block distributes the autorecloser outputs to the phases currently active, as determined by the first part of the function.

The connections between these functions (shown as passive lines) are internal and not visible in the application configuration.

Inputs to the function consist of per phase trip / pickup signals from various protection functions, and the states of all poles, if any of them is / are open. Outputs from the function consist of per phase breaker open / close commands, and lockout signals.

Input and output function blocks are basically support function blocks. Though these functions are instantiated independently, they don't have their own settings. The core autorecloser function which is called SDARREC and all the parameter settings to the
overall functionality are updated only in this function block. This is the reason the overall Autorecloser (AR) functionality is called with the same name.

5.2.1 Identification

5.2.2 Function block

![Figure 139: SDARREC 79 core function block](image)

5.2.2.1 Supporting function blocks

![Figure 140: SDAIGGIO function blocks (1..6)](image)

5.2.3 Functionality

About 80 to 85 percent of faults in the MV overhead lines are transient and automatically cleared with a momentary de-energization of the line. The rest of the faults, 15 to 20 percent, can be cleared by longer interruptions. The de-energization of the fault location...
for a selected time period is implemented through automatic reclosing, during which most of the faults can be cleared.

In case of a permanent fault, the automatic reclosing is followed by final tripping. A permanent fault must be located and cleared before the fault location can be re-energized.

In a distribution network, bulk of the load is single phase / independent. It is therefore not necessary to de-energize all three phases for a single phase fault. The single phase auto-reclose function SDARREC can be used for auto-reclosing together with any circuit breaker that has the characteristics required for single phase auto-reclosing. For multi-phase asymmetrical faults, the trip should occur on the tripped as well as the picked up phases.

The function provides five programmable auto-reclose shots which can perform one to five successive auto-reclosings of desired type and duration, for instance one high-speed and one delayed auto-reclosing.

The SDARREC allows single phase operations, where the number of poles operating together can be one, two or three, depending on fault conditions. Once a fault occurs, the "Active Phase Detection" function determines which phases are to be active for the next reclose shot.

The autorecloser function used by the SDARREC receives equivalent “TRIP”, “PoleStatus”, etc. signals that are formed by integrating individual phase signals from the active phases. It performs its logic and generates equivalent OPEN / RECLOSE / LOCKOUT etc. signals. Subsequent logic then routes these signals to the appropriate, “active” phase outputs.

### 5.2.3.1 Single phase tripping

The single phase tripping function is controlled by the settings SinglePhaseMode and Shot Mode 1...5. The SinglePhaseMode setting can have three values, OPUP, OOAP and APAT.

The value OPUP stands for “Only Picked Up Phases”. With this value, the SDARREC will trip the tripped and picked up phases. Unfaulted phase(s) will stay closed.

The value OOAP stands for “One Or All Phases”. With this value, the SDARREC will trip the tripped and picked up phases as in the OPUP mode. Additionally, it will also look at whether only one phase is going to be left closed as a result of the OPUP logic. If so, it will trip the remaining phase as well.

The value APAT stands for “All Poles All the Time”, and effectively disables the single phase mode. All the poles are operated always.

In addition, the Shot Mode settings can override the SinglePhaseMode setting for each specific reclose shot, and on a per autorecloser input basis. These settings values can be either 0 or 1. When the value is 0, the SinglePhaseMode setting determines the number of phases opening. When the value is 1, all three poles will open, regardless of the SinglePhaseMode setting.
5.2.3.2 Protection signal definition

The Control line setting defines which of the initiation signals are protection pickup and trip signals and which are not. With this setting, the user can distinguish the blocking signals from the protection signals. The Control line setting is a bit mask, that is, the lowest bit controls the INIT_1 line and the highest bit the INIT_6 line. Some example combinations of the Control line setting are as follows:

<table>
<thead>
<tr>
<th>Control line setting</th>
<th>INIT_1</th>
<th>INIT_2</th>
<th>INIT_3</th>
<th>INIT_4</th>
<th>INIT_5</th>
<th>INIT_6</th>
</tr>
</thead>
<tbody>

<td>prot</td>
<td>prot</td>
<td>prot</td>
<td>prot</td>
</tr>
</tbody>
</table>

**Table 293: Control line setting definition**

- **prot** = protection signal
- **other** = non-protection signal

When the corresponding bit or bits in both the Control line setting and the INIT_X line are TRUE:

- The CLOSE_CB output is blocked until the protection is reset
- If the INIT_X line defined as the protection signal is activated during the discrimination time, the AR function goes to lockout
- If the INIT_X line defined as the protection signal stays active longer than the time set by the Max trip time setting, the AR function goes to lockout (long trip)
- The UNSUC_RECL output is activated after a pre-defined two minutes (alarming ground-fault).

It is emphasized that the three phases of the same protection function should be fed to the same INIT input to the autorecloser.

5.2.4 Operation principle

The function can be enabled and disabled with the Operation setting. The corresponding parameter values are “On” and “Off”.

⚠️ Setting the Operation setting to “Off” will prevent tripping by any protection function!

The reclosing operation can be enabled and disabled with the Reclosing operation setting. This setting does not disable the function, only the reclosing functionality. The setting has three parameter values: “On”, “External Ctl” and “Off”. The setting value “On” enables the reclosing operation and “Off” disables it. When the setting value “External Ctl” is selected, the reclosing operation is controlled with the RECL_ON input.
Figure 142: Logical overview diagram with internal connections in overall Autoreclosing functionality

The logical diagram showing internal connections between SDAIGGIO input blocks, SDARREC Core block and SDAOGGIO output block is shown in Figure 142.

The 3 sections of overall Autorecloser functionality explained below.
5.2.4.1 Active Phases Determination with SDAIGGIO Blocks

Figure 143: SDAIGGIO function block

The input section, consists of 6 modular supporting functional blocks called SDAIGGIO1..6, collates various signal phase trip / pickup signals from different single phase protection functions. It uses the logic described below to determine which phases are to be activated for this reclose cycle, and tailors its outputs to be fed to the autorecloser / output functions.

**SDAIGGIO 1..6**

A functional block diagram is shown in Figure 143. It shows one SDAIGGIO block for autorecloser function input. There are six such blocks altogether. They are not independent function blocks and they are instantiated as part of overall autoreclosing functionality.

The Autoreclosing function allows a picked up / unfaulted phase to trip along with the faulted phase. The picked up phase is tripped, as it is presumed to be a part of the same multi-phase fault, though with a lower fault current. An unfaulted phase may also be tripped in case it is not advisable for only one phase to remain energized after the breaker opens.
Section 5
Control functions

Figure 144: Active phase determination

This feature is implemented by the SDAIGGIO block. It accepts trip / pickup signals from a protection function and determines (based on settings) which phases are to be tripped. It then generates one TRIP output, along with which phases are active.

The SDAIGGIO feature consists of the following three modes:

**OPUP: (Only Picked Up Phases)**

- For a phase fault, once a phase protection function generates a trip command, the other phases are examined for a picked up state. If another phase is in a "picked up" state, that phase is also issued a trip command.
- For a neutral fault, all the picked up phases are tripped. If no phase is picked up, then all phases are tripped. The neutral picked up signal is not used.
- Reclose operations are synchronized between poles.

**OOAP: (One Or All Phases)**

- In this case, the trip decision is made in steps:
  - First, the OPUP mode is used to determine which phase(s) will be tripped.
  - Second, the state of poles is considered. A pole may already be open due to an earlier trip / lockout or a manual / scada operation.
  - If the decision in the first step will leave exactly one phase in a CLOSED state, then that phase is also issued a trip command.
  - As an example, consider the following sequence:
    - “A” phase sees a fault; “B” and “C” were not picked up. Only the “A” phase is tripped, and locks out after the reclose cycle.
• Later, after “A” phase locks out, but before it is restored, “B” phase sees a fault, and “C” is not picked up. Using the OPUP logic, only the “B” phase would have been tripped. However, this would leave only the “C” phase CLOSED. In the OOAP mode, the “C” phase will also be tripped, though it does not have a fault.

• Reclose operations are synchronized between poles.

APAT: (All Poles All the Time)

• In this case, the single phase function is disabled. The recloser operates as a three phase recloser. However, we still have three actuators and three position sensors for the three poles, so the controls must operate independently. However, for any fault, the trip, reclose, lockout signals are issued to all three phases.

SDARREC “OR” logic function

The SDARREC has six SDAIGGIO functions. Each will operate independent of the others. The “OR” logic function combines the “Active Phase” outputs from the six SDAIGGIO blocks and generates one set of combined “Active Phase” outputs for use by the output SDAOOGGIO function. Its functional block is as shown in Figure 144 above. This entire "OR" logic along with output channels of SDAGGIO blocks connected to SDARREC function block through fixed internal connections which are not visible in the application configuration.

5.2.4.2 Autorecloser function (Core)

The autorecloser function accepts "TRIP" signals from the input functions and generates the appropriate reclose / open / lockout signals, for use by the output function. The operation of the auto-reclose function can be described by using a module diagram (Figure 146). All the blocks in the diagram are explained in the next sections.
Signal collection

When the protection trips, the initiation of autoreclose shots is in most applications executed with the \texttt{INIT\_1...6} inputs.
In total, the AR function contains six separate initiation lines used for the initiation or blocking of the auto-reclose shots.

The auto-reclose shot is initiated with a trip signal of the protection function. The auto-reclose starts when the protection operate delay time elapses. Normally, all trip and start signals are used to initiate an auto-reclose shot and trip the circuit breaker. If any of the input signals INIT_X are used for blocking, the corresponding bit in the Tripping line setting must be FALSE. This is to ensure that the circuit breaker does not trip from that signal, that is, the signal does not activate the OPEN_CB output. The default value for the...
setting is “63”, which means that all initiation signals activate the OPEN_CB output. The lowest bit in the Tripping line setting corresponds to the INIT_1 input, the highest bit to the INIT_6 line.

**Shot initiation**

![Diagram of shot initiation]

**Figure 149:**  Example of an autoreclose program with a reclose scheme matrix

In the AR function, each shot can be programmed to locate anywhere in the reclose scheme matrix. The shots are like building blocks used to design the reclose program. The building blocks are called CBBs. All blocks are alike and have settings which give the attempt number (columns in the matrix), the initiation or blocking signals (rows in the matrix) and the reclose time of the shot.

The settings related to CBB configuration are:

- **First...Seventh reclose time**
- **Init signals CBB1...CBB7**
- **Blk signals CBB1...CBB7**
- **Shot number CBB1...CBB7**

The reclose time defines the open and dead times, that is, the time between the OPEN_CB and the CLOSE_CB commands. The Init signals CBBx setting defines the initiation signals. The Blk signals CBBx setting defines the blocking signals that are related to the
Control functions

CBB (rows in the matrix). The Shot number CBB1...CBB7 setting defines which shot is related to the CBB (columns in the matrix). For example, CBB1 settings are:

- First reclose time = 1.0s
- Init signals CBB1 = 7 (three lowest bits: 000111 = 7)
- Blk signals CBB1 = 16 (the fifth bit: 010000 = 16)
- Shot number CBB1 = 1

CBB2 settings are:

- Second reclose time = 10s
- Init signals CBB2 = 6 (the second and third bits: 000110 = 6)
- Blk signals CBB2 = 16 (the fifth bit: 010000 = 16)
- Shot number CBB2 = 2

CBB3 settings are:

- Third reclose time = 30s
- Init signals CBB3 = 4 (the third bit: 000100 = 4)
- Blk signals CBB3 = 16 (the fifth bit: 010000 = 16)
- Shot number CBB3 = 3

CBB4 settings are:

- Fourth reclose time = 0.5s
- Init signals CBB4 = 8 (the fourth bit: 001000 = 8)
- Blk signals CBB4 = 0 (no blocking signals related to this CBB)
- Shot number CBB4 = 1

If a shot is initiated from the INIT_1 line, only one shot is allowed before lockout. If a shot is initiated from the INIT_3 line, three shots are allowed before lockout.

A sequence initiation from the INIT_4 line leads to a lockout after two shots. In a situation where the initiation is made from both the INIT_3 and INIT_4 lines, a third shot is allowed, that is, CBB3 is allowed to start. This is called conditional lockout. If the initiation is made from the INIT_2 and INIT_3 lines, an immediate lockout occurs.

The INIT_5 line is used for blocking purposes. If the INIT_5 line is active during a sequence start, the reclose attempt is blocked and the AR function goes to lockout.

If more than one CBBs are started with the shot pointer, the CBB with the smallest individual number is always selected. For example, if the INIT_2 and INIT_4 lines are active for the second shot, that is, the shot pointer is 2, CBB2 is started instead of CBB5.

Even if the initiation signals are not received from the protection functions, the AR function can be set to continue from the second to the fifth reclose shot. The AR function can, for example, be requested to automatically continue with the sequence when the circuit breaker fails to close when requested. In such a case, the AR function issues a CLOSE_CB command. When the wait close time elapses, that is, the closing of the circuit breaker fails, the next shot is automatically started. Another example is the embedded generation on the power line, which can make the synchronism check fail and prevent the
reclosing. If the autoreclose sequence is continued to the second shot, a successful synchronous reclosing is more likely than with the first shot, since the second shot lasts longer than the first one.

Automatic initiation can be selected with the *Auto initiation Cnd* setting to be the following:

- Not allowed: no automatic initiation is allowed
- When the synchronization fails, the automatic initiation is carried out when the auto wait time elapses and the reclosing is prevented due to a failure during the synchronism check
- When the circuit breaker does not close, the automatic initiation is carried out if the circuit breaker does not close within the wait close time after issuing the reclose command

**Figure 150:** Logic diagram of auto-initiation sequence detection

Automatic initiation can be selected with the *Auto initiation Cnd* setting to be the following:
- Both: the automatic initiation is allowed when synchronization fails or the circuit breaker does not close.

The *Auto init* parameter defines which \texttt{INIT\_X} lines are activated in the auto-initiation. The default value for this parameter is “0”, which means that no auto-initiation is selected.

![Diagram](image)

**Figure 151:** Example of an auto-initiation sequence with synchronization failure in the first shot and circuit breaker closing failure in the second shot

In the first shot, the synchronization condition is not fulfilled (\texttt{SYNC} is FALSE). When the auto wait timer elapses, the sequence continues to the second shot. During the second reclosing, the synchronization condition is fulfilled and the close command is given to the circuit breaker after the second reclose time has elapsed.

After the second shot, the circuit breaker fails to close when the wait close time has elapsed. The third shot is started and a new close command is given after the third reclose time has elapsed. The circuit breaker closes normally and the reclaim time starts. When the reclaim time has elapsed, the sequence is concluded successful.

**Shot initiation and shot sequencing Possibilities**

The autoreclose function is initiated after the protection has detected a fault, issued a trip and opened the breaker. One input is enough for initiating the function.

The function consists of six individual initiation lines \texttt{INIT\_1}, \texttt{INIT\_2}... \texttt{INIT\_6}. The user can use as many of the initiation lines as required. Using only one line makes setting easier, whereas by using multiple lines, higher functionality can be achieved. Basically, there are no differences between the initiation lines.
The operation of a CBB consists of two parts: initiation and execution. In the initiation part, the status of the initiation lines is compared to the CBB settings. In order to allow the initiation at any of the initiation line activation, the corresponding switch in the Init signals CBB parameter must be set to TRUE. In order to block the initiation, the corresponding switch in the Blk signals CBB parameter must be set to TRUE.

If any of the initiation lines set with the Init signals CBB parameter is active and no initiation line causes blocking, the CBB requests for execution.
Each CBB has individual Init signals CBB and Blk signals CBB settings. Therefore, each initiation line can be used for both initiating and blocking any or all autoreclose shots.

Other conditions that must be fulfilled before any CBB can be initiated are, for example, the closed position of the circuit breaker.

The autoreclose sequence is implemented by using up to seven CBBs. For example, if the user wants a sequence of three shots then only the first three CBBs are needed. Using building blocks instead of fixed shots gives enhanced flexibility, allowing multiple and adaptive sequences.

Each CBB is identical. The Shot number CBB setting defines at which point in the autoreclose sequence the CBB should be performed, that is, whether the particular CBB is going to be the first, second, third, fourth or fifth shot.

During the initiation of a CBB, the conditions of initiation and blocking are checked. This is done for all CBBs simultaneously. Each CBB that fulfils the initiation conditions requests an execution.

The function also keeps track of shots already performed. That is, at which point the autoreclose sequence is from shot 1 to lockout. For example, if shots 1 and 2 have already been performed, only shots 3 to 5 are allowed.

Additionally, the Enable shot jump setting gives two possibilities:

- Only such CBBs that are set for the next shot in the sequence can be accepted for execution. For example, if the next shot in the sequence should be shot 2, a request from CBB set for shot 3 is rejected.
- Any CBB that is set for the next shot or any of the following shots can be accepted for execution. For example, if the next shot in the sequence should be shot 2, also CBBs that are set for shots 3, 4 and 5 are accepted. In other words, shot 2 can be ignored.
In case there are multiple CBBs allowed for execution, the CBB with the smallest number is chosen. For example, if CBB2 and CBB4 request an execution, CBB2 is allowed to execute the shot.

The autoreclose function can perform up to five autoreclose shots or cycles.

**Shot pointer controller**

The execution of a reclose sequence is controlled by a shot pointer. It can be adjusted with the `SHOT_PTR` monitored data.

The shot pointer starts from an initial value “1” and determines according to the settings whether or not a certain shot is allowed to be initiated. After every shot, the shot pointer value increases. This is carried out until a successful reclosing or lockout takes place after a complete shot sequence containing a total of five shots.

![Figure 154: Shot pointer function](image)

Every time the shot pointer increases, the reclaim time starts. When the reclaim time ends, the shot pointer sets to its initial value, unless no new shot is initiated. The shot pointer increases when the reclose time elapses or at the falling edge of the `INC_SHOTP` signal.

When `SHOT_PTR` has the value six, the AR function is in a so called pre-lockout state. If a new initiation occurs during the pre-lockout state, the AR function goes to lockout. Therefore, a new sequence initiation during the pre-lockout state is not possible.

The AR function goes to the pre-lockout state in the following cases:

- When the AR function is active, it stays in a pre-lockout state for the time defined by the reclaim time
- When all five shots have been executed
- When the frequent operation counter limit is reached. A new sequence initiation forces the AR function to lockout.
Reclose controller

The reclose controller calculates the reclose, discrimination and reclaim times. The reclose time is started when the INPRO signal is activated, that is, when the sequence starts and the activated CBB defines the reclose time.

When the reclose time has elapsed, the CLOSE_CB output is not activated until the following conditions are fulfilled:

- The SYNC input must be TRUE if the particular CBB requires information about the synchronism
- All AR initiation inputs that are defined protection lines (using the Control line setting) are inactive
- The circuit breaker is open
- The circuit breaker is ready for the close command, that is, the CB_READY input is TRUE.

If at least one of the conditions is not fulfilled within the time set with the Auto wait time parameter, the autoreclose sequence is locked.

The synchronism requirement for the CBBs can be defined with the Synchronization set setting, which is a bit mask. The lowest bit in the Synchronization set setting is related to CBB1 and the highest bit to CBB7. For example, if the setting is set to “1”, only CBB1 requires synchronism. If the setting is it set to “7”, CBB1, CBB2 and CBB3 require the SYNC input to be TRUE before the reclosing command can be given.

![Figure 155: Initiation during discrimination time - AR function goes to lockout](image)

The discrimination time starts when the close command CLOSE_CB has been given. If a pickup input is activated before the discrimination time has elapsed, the AR function goes to lockout. The default value for each discrimination time is zero. The discrimination time can be adjusted with the Dsr time shot 1…4 parameter.
When the **LOCKED** output is active, the AR function is in lockout. This means that new sequences cannot be initialized, because AR is insensitive to initiation commands. It can be released from the lockout state in the following ways:

- The function is reset through communication with the **RsRec** parameter
- The lockout is automatically reset after the reclaim time, if the *Auto lockout reset* setting is in use.

If the *Auto lockout reset* setting is not in use, the lockout can be released only with the **RsRec** parameter.

The AR function can go to lockout for many reasons:

- The **INHIBIT_RECL** input is active
- All shots have been executed and a new initiation is made (final trip)
- The time set with the *Auto wait time* parameter expires and the automatic sequence initiation is not allowed because of a synchronization failure
- The time set with the *Wait close time* parameter expires, that is, the circuit breaker does not close or the automatic sequence initiation is not allowed due to a closing failure of the circuit breaker
- A new shot is initiated during the discrimination time
- The time set with the *Max wait time* parameter expires, that is, the master unit does not release the slave unit
- The frequent operation counter limit is reached and new sequence is initiated. The lockout is released when the recovery timer elapses
- The protection trip signal has been active longer than the time set with the *Max wait time* parameter since the shot initiation
• The circuit breaker is closed manually during an autoreclose sequence and the manual close mode is FALSE.

**Protection coordination controller**

The PROT_CRD output is used for controlling the protection functions. In several applications, such as fuse-saving applications involving down-stream fuses, tripping and initiation of shot 1 should be fast (instantaneous or short-time delayed). The tripping and initiation of shots 2, 3 and definite tripping time should be delayed.

In this example, two overcurrent elements 51P and 50P-2 are used. 50P-2 is given an instantaneous characteristic and 51P is given a time delay.

The PROT_CRD output is activated, if the SHOT_PTR value is higher than the value defined with the *Protection crd limit* setting and all initialization signals have been reset. The PROT_CRD output is reset under the following conditions:

- If the cut-out time elapses
- If the reclaim time elapses and the AR function is ready for a new sequence
- If the AR function is in lockout or disabled, that is, if the value of the *Protection crd mode* setting is “AR inoperative” or “AR inop, CB man”.

The PROT_CRD output can also be controlled with the *Protection crd mode* setting. The setting has the following modes:

- “no condition”: the PROT_CRD output is controlled only with the *Protection crd limit* setting
- “AR inoperative”: the PROT_CRD output is active, if the AR function is disabled or in the lockout state, or if the INHIBIT_RECL input is active
- “CB close manual”: the PROT_CRD output is active for the reclaim time if the circuit breaker has been manually closed, that is, the AR function has not issued a close command
- “AR inop, CB man”: both the modes “AR inoperative” and “CB close manual” are effective
- “always”: the PROT_CRD output is constantly active
If the Protection crd limit setting has the value “1”, the instantaneous three-phase overcurrent protection function 50P-3 is disabled or blocked after the first shot.

**Circuit breaker controller**

Circuit breaker controller contains two features: SOTF and frequent-operation counter. SOTF protects the AR function in permanent faults.

The circuit breaker position information is controlled with the CB closed Pos status setting. The setting value “TRUE” means that when the circuit breaker is closed, the CB_POS input is TRUE. When the setting value is “FALSE”, the CB_POS input is FALSE, provided that the circuit breaker is closed. The reclose command pulse time can be controlled with the Close pulse time setting: the CLOSE_CB output is active for the time set with the Close pulse time setting. The CLOSE_CB output is deactivated also when the circuit breaker is detected to be closed, that is, when the CB_POS input changes from open state to closed state. The Wait close time setting defines the time after the CLOSE_CB command activation, during which the circuit breaker should be closed. If the closing of circuit breaker does not happen during this time, the autoreclose function is driven to lockout or, if allowed, an auto-initiation is activated.

The main motivation for autoreclosing to begin with is the assumption that the fault is temporary by nature, and that a momentary de-energizing of the power line and an automatic reclosing restores the power supply. However, when the power line is manually energized and an immediate protection trip is detected, it is very likely that the fault is of a permanent type. An example of a permanent fault is, for example, energizing a power line into a forgotten grounding after a maintenance work along the power line. In such cases, SOTF is activated, but only for the reclaim time after energizing the power line and only when the circuit breaker is closed manually and not by the AR function.

SOTF disables any initiation of an autoreclose shot. The energizing of the power line is detected from the CB_POS information.

SOTF is activated when the AR function is enabled or when the AR function is started and the SOTF should remain active for the reclaim time.
When SOTF is detected, the parameter SOTF is active.

- If the Manual close mode setting is set to FALSE and the circuit breaker has been manually closed during an autoreclose shot, the AR unit goes to an immediate lockout.

- If the Manual close mode setting is set to TRUE and the circuit breaker has been manually closed during an autoreclose shot (the INPRO is active), the shot is considered as completed.

- When SOTF starts, reclaim time is restarted, provided that it is running.

The frequent-operation counter is intended for blocking the autoreclose function in cases where the fault causes repetitive autoreclose sequences during a short period of time. For instance, if a tree causes a short circuit and, as a result, there are autoreclose shots within a few minutes interval during a stormy night. These types of faults can easily damage the circuit breaker if the AR function is not locked by a frequent-operation counter.

The frequent-operation counter has three settings:

- Frq Op counter limit
- Frq Op counter time
- Frq Op recovery time

The Frq Op counter limit setting defines the number of reclose attempts that are allowed during the time defined with the Frq Op counter time setting. If the set value is reached within a pre-defined period defined with the Frq Op counter time setting, the AR function goes to lockout when a new shot begins, provided that the counter is still above the set limit. The lockout is released after the recovery time has elapsed. The recovery time can be defined with the Frq Op recovery time setting.

If the circuit breaker is manually closed during the recovery time, the reclaim time is activated after the recovery timer has elapsed.

### 5.2.4.3 Output Interface with SDAOGGIO Block

This consists of the function block SDAOGGIO, shown in Figure 158 below.
Section 5
Control functions

This module combines the outputs from the AutoRecloser function and the “Active Phase Detect” function to route the TRIP / RECLOSE / LOCKOUT signals to the phases that are active for the reclose cycle in progress currently.

The autorecloser function requires a single “Pole Status” signal for its internal needs. However, the SDARREC function can allow operations on more than one phase at a time. Two or three phases can be active at the same time.

When more than one pole is active, the SDAOGGIO will generate an equivalent “pole status” signal for the AutoReclose function. Although all the TRIP / RECLOSE commands are issued simultaneously, one pole may operate with a delay compared to the other(s). In such cases, the SDAOGGIO will wait for all the active poles to complete their transition before generating a valid status to be used by the AutoRecloser function.

5.2.5 Zone sequence coordination

Zone sequence coordination is used in the zone sequence between local protection units and downstream devices. At the falling edge of the INC_SHOPT line, the value of the shot pointer is increased by one, unless a shot is in progress or the shot pointer already has the maximum value.

The falling edge of the INC_SHOPT line is not accepted if any of the shots are in progress.
5.2.6 Counters

The AR function contains six counters. Their values are stored in a semi-retain memory. The counters are increased at the rising edge of the reclose command. The counters count the following situations:

- **COUNTER**: counts every reclose command activation
- **CNT_SHOT1**: counts reclose commands that are executed from shot 1
- **CNT_SHOT2**: counts reclose commands that are executed from shot 2
- **CNT_SHOT3**: counts reclose commands that are executed from shot 3
- **CNT_SHOT4**: counts reclose commands that are executed from shot 4
- **CNT_SHOT5**: counts reclose commands that are executed from shot 5

The counters are disabled through communication with the $DsaCnt$ parameter. When the counters are disabled, the values are not updated.

The counters are reset through communication with the $RsCnt$ parameter.

5.2.7 Application

Modern electric power systems can deliver energy to users very reliably. However, different kind of faults can occur. Protection relays play an important role in detecting failures or abnormalities in the system. They detect faults and give commands for corresponding circuit breakers to isolate the defective element before excessive damage or a possible power system collapse occurs. A fast isolation also limits the disturbances caused for the healthy parts of the power system.

The faults can be transient, semi-transient or permanent. For example, a permanent fault in power cables means that there is a physical damage in the fault location that must first be located and repaired before the network voltage can be restored.

In overhead lines, the insulating material between phase conductors is air. The majority of the faults are flash-over arcing faults caused by lightning, for example. Only a short interruption is needed for extinguishing the arc. These faults are transient by nature.

A semi-transient fault can be caused for example by a bird or a tree branch falling on the overhead line. The fault disappears on its own if the fault current burns the branch or the wind blows it away.

Transient and semi-transient faults can be cleared by momentarily de-energizing the power line. Using the autoreclose function minimizes interruptions in the power system service and brings the power back on-line quickly and effortlessly.

The basic idea of the autoreclose function is simple. In overhead lines, where the possibility of self-clearing faults is high, the autoreclose function tries to restore the power by reclosing the breaker. This is a method to get the power system back into normal operation by removing the transient or semi-transient faults. Several trials, that is, autoreclose shots are allowed. If none of the trials is successful and the fault persists, definite final tripping follows.
The autoreclose function can be used with every circuit breaker that has the ability for a reclosing sequence. In 79 autoreclose function the implementing method of autoreclose sequences is patented by ABB.

Table 294: Important definitions related to autoreclosing

<table>
<thead>
<tr>
<th>Definition</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>autoreclose shot</td>
<td>an operation where after a preset time the breaker is closed from the breaker tripping caused by protection</td>
</tr>
<tr>
<td>autoreclose sequence</td>
<td>a predefined method to do reclose attempts (shots) to restore the power system</td>
</tr>
<tr>
<td>SOTF</td>
<td>If the protection detects a fault immediately after an open circuit breaker has been closed, it indicates that the fault was already there. It can be, for example, a forgotten grounding after maintenance work. Such closing of the circuit breaker is known as switch on to fault. Autoreclosing in such conditions is prohibited.</td>
</tr>
<tr>
<td>final trip</td>
<td>Occurs in case of a permanent fault, when the circuit breaker is opened for the last time after all programmed autoreclose operations. Since no autoreclosing follows, the circuit breaker remains open. This is called final trip or definite trip.</td>
</tr>
</tbody>
</table>

5.2.7.1 Single Phase Tripping

The RER620 single-phase tripping and reclosing option is advantageous for use on many electric utility distribution systems, including rural, residential and some commercial loads. It provides a control capability function of the recloser to trip and/or lockout whenever there is a fault on one-phase, two-phases or three-phases. This feature allows an electric utility to prevent unnecessary three-phase interruptions and outages of their distribution network where a majority of outages can be attributed to single-phase transient type faults thereby improving the overall power system reliability and quantity of power delivered to customers on the distribution feeder.

Overview of the features in single-phase tripping

As an example of single-phase operation of an RER620 with a recloser, imagine that the recloser is protecting a rural three-phase line. Suppose that a fault occurs on A-phase, where the fault is permanent and there is no fuse between the recloser and the fault. A conventional three-phase recloser will trip for two instantaneous operations followed by two time-delayed operations. The single-phase fault on A-phase will cause all customers downstream to experience three interruptions of power and an outage until the fault is repaired, cleared and the recloser restored to normal operation. The RER620 with single-phase tripping can operate the recloser for the same single-phase fault on A-phase as a single-pole trip, reclose and lockout. This provides a significant advantage to 67% of the customers downstream of the fault since their power is not interrupted. The operation of single-phase operation will trip for two instantaneous operations, two time-delayed operation and lockout on the A-phase pole. Since the fault is a permanent single-phase-to-ground fault, (e.g. A-N), the load connected to A-phase will experience an outage but the other two phases (e.g. B-phase and C-phase) will not experience any interruption of power and will stay energized.

The single phase tripping option is designed to be extremely flexible in order to meet the most demanding requirements. Listed below are brief descriptions of the features for single-phase and three-phase tripping operation:

RER620s supplied with the single phase tripping option consist of the same hardware (front panel and modules) as the standard three phase units. Settings for single phase
tripping RER620s, however, vary from the three phase units. With this option, you must select whether you want to use the single phase tripping option or not in SDARREC Settings. In three-phase tripping mode, the RER620 operates in the same manner as a unit without the single-phase tripping option. Single-phase tripping is disabled. Three-phase tripping is enabled.

In single-phase tripping mode, the phase that detects fault current (e.g., current above the pickup threshold level) will initiate the recloser respective pole to trip open. In this mode, for each protection group, the user may choose one of three modes of operation for single-phase tripping: APAT (All Poles All the Time), OPUP (Only Picked Up Phases) and OOAP (One Or All Phases).

**Conditions on Single Phase Tripping**

- When there is a single-phase fault and there is another phase that becomes involved, the additional phase will immediately time out and trip on the curve associated with the step that the other phase has tripped on last. However, all tripped phases will reclose in tandem.

- When a single phase has locked out, the reset timer will count down from its set value in the recloser settings. If another phase becomes involved before the reset time expires, that phase will operate one shot to lockout. If, alternatively, the reset timer has expired, the additional involved phase will go through the full sequence of programmed operations.

- In single-phase tripping, the phase fault current must be greater than the phase element pickup for the single-phase trip to occur. If the fault current is above the neutral setting, but below the phase setting, a three-phase trip will occur.

- In the case where both the phase and ground element pick up (all phases must be closed for neutral pickup), the trip time for the involved phases will be based on the faster of the phase trip or the ground setting.

- After a single phase trip or lockout operation, all ground tripping is de-energized. This prevents nuisance tripping of adjacent phases afterwards, due to load imbalance.

**OPUP Mode - Only Picked Up Phases**

If OPUP is selected, any respective phase that detects fault current by the RER620 is actuated to open the respective pole of the recloser. The option for OPUP also allows each pole on the recloser to open independently if the RER620 detects fault current on any of the other two phases.

For example, suppose that a fault is detected on phase B. The RER620 will sense this pickup and initiate a binary output signal from the RER620 to the recloser, the recloser will trip open phase B and await timing from the RER620 for subsequent reclose or lockout. Now suppose that during the pickup and subsequent trip of phase B, the RER620 senses another fault on phase A. The RER620 will detect that fault and initiate a binary output signal from the RER620 to the recloser for pole A, the recloser will trip open phase A and then await timing from the RER620 for reclose or lockout. Comparable sequences may occur and operation of the RER620 will continue to operate for phase C or any combination of phase(s) caused by excessive load or fault current.
OOAP Mode - One Or All Phases

In this mode, if a single-phase fault is detected or picked up on one pole, a single-phase trip will occur as in the case of OPUP mode. However, if a combination of two or three phases pickup or detect a fault, then the RER620 will initiate a binary trip output to the recloser for all three poles to trip.

For example, consider a situation where the distribution load has motors connected onto the distribution line. If a single-phase fault occurred on any phase of the line, the RER620 should initiate a trip of all three phases, OOAP, to prevent the three-phase motors from single phasing. A three-phase motor may continue to run with the loss of a single-phase, but it will overheat. In addition, a stopped three-phase motor that is attempting to start with the loss of a single-phase will cause overheating in the motor. For this application, a distribution line with three-phase motors should implement OOAP on single-phase faults.

Some common examples:

- The recloser is set to trip on a single-phase fault in single-phase fashion, but lockout in three-phase fashion (OOAP). A fault is detected and the recloser trips open on one phase and will lockout on all three phases if the fault detected is a permanent fault.

- The recloser is set to trip on a single-phase fault (OOAP). A two-phase fault is detected and the recloser trips open on all three phases and will lockout on all three phases if the fault detected is a permanent fault.
Summary of Single-Phase Tripping

The following diagrams illustrate overall logical diagram, the state of different poles for different faults, based on the settings in use.
Figure 160: Summary of single-phase tripping

5.2.8 Configuration examples

Fault Case 1:
A phase: High Fault Current
B phase: Low Fault Current
C phase: Load Current

Fault Case 2:
A phase: High Fault Current
B phase: Low Fault Current
C phase: Already Open

Fault Case 3:
A phase: High Fault Current
B phase: Load Current
C phase: Already Open

Fault Case 4:
A phase: High Fault Current
B phase: Load Current
C phase: Already Open

It is possible to create several sequences for a configuration.

Autoreclose sequences for overcurrent and non-directional ground-fault protection applications where high speed and delayed autoreclosings are needed can be as follows:
**Example 1**

The sequence is implemented by two shots which have the same reclose time for all protection functions, namely 50P-1, 51P and 51N/G. The initiation of the shots is done by activating the trip signals of the protection functions.

![Autoreclose sequence with two shots](image)

In this case, the sequence needs two CBBs. The reclosing times for shot 1 and shot 2 are different, but each protection function initiates the same sequence. The CBB sequence is as follows:

![Two shots with three initiation lines](image)

### Table 295: Settings for configuration example 1

<table>
<thead>
<tr>
<th>Setting name</th>
<th>Setting value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Shot number CBB1</td>
<td>1</td>
</tr>
<tr>
<td>Init signals CBB1</td>
<td>7 (lines 1,2 and 3 = 1+2+4 = 7)</td>
</tr>
<tr>
<td>First reclose time</td>
<td>0.3s (an example)</td>
</tr>
<tr>
<td>Shot number CBB2</td>
<td>2</td>
</tr>
<tr>
<td>Init signals CBB2</td>
<td>7 (lines 1,2 and 3 = 1+2+4 = 7)</td>
</tr>
<tr>
<td>Second reclose time</td>
<td>15.0s (an example)</td>
</tr>
</tbody>
</table>
Example 2

There are two separate sequences implemented with three shots. Shot 1 is implemented by CBB1 and it is initiated with the high stage of the overcurrent protection (50P-1). Shot 1 is set as a high-speed autoreclosing with a short time delay. Shot 2 is implemented with CBB2 and meant to be the first shot of the autoreclose sequence initiated by the low stage of the overcurrent protection (51P) and the low stage of the non-directional ground-fault protection (51N/G). It has the same reclose time in both situations. It is set as a high-speed autoreclosing for corresponding faults. The third shot, which is the second shot in the autoreclose sequence initiated by 51P or 51N/G, is set as a delayed autoreclosing and executed after an unsuccessful high-speed autoreclosing of a corresponding sequence.

![Autoreclose sequence with two shots with different shot settings according to initiation signal](image)

**Figure 164:** Autoreclose sequence with two shots with different shot settings according to initiation signal

- $t_{HSAR}$: Time delay of high-speed autoreclosing, here: First reclose time
- $t_{ DAR}$: Time delay of delayed autoreclosing, here: Second reclose time
- $t_{>>}$: Operating time for the 50P-1 protection stage to clear the fault
- $t_{P, or io}$: Operating time for the 51P or 51N/G protection stage to clear the fault
- $t_{CB,O}$: Operating time for opening the circuit breaker
- $t_{CB,C}$: Operating time for closing the circuit breaker

In this case, the number of needed CBBs is three, that is, the first shot's reclosing time depends on the initiation signal. The CBB sequence is as follows:
If the sequence is initiated from the \texttt{INIT\_1} line, that is, the overcurrent protection high stage, the sequence is one shot long. On the other hand, if the sequence is initiated from the \texttt{INIT\_2} or \texttt{INIT\_3} lines, the sequence is two shots long.

5.3.2 Function block

Figure 166: Function block

5.3.3 Functionality

The synch-check function checks the condition across the circuit breaker from separate power system parts and gives the permission to close the circuit breaker. SECRSYN includes the functionality of synch-check and energizing check.

Asynchronous operation mode is provided for asynchronously running systems. The main purpose of the asynchronous operation mode is to provide a controlled closing of circuit breakers when two asynchronous systems are connected.

The synch-check operation mode checks that the voltages on both sides of the circuit breaker are perfectly synchronized. It is used to perform a controlled reconnection of two systems which are divided after islanding and it is also used to perform a controlled reconnection of the system after reclosing.

The energizing check function checks that at least one side is dead to ensure that closing can be done safely.

The function contains a blocking functionality. It is possible to block function outputs and timers if desired.
The energizing check function measures the bus and line voltages and compares them to both high and low threshold detectors. The output is given only when the actual measured quantities match the set conditions.

The synch-check function in the continuous mode measures the conditions across the circuit breaker from separate power system parts and compares them to the set limits. When all the measured quantities are within their set limits simultaneously, that is, the systems are in synchronism, the output for allowing or executing the circuit breaker closing is activated.

The synch-check function in the command mode measures the conditions across the circuit breaker and also determines the angle change occurring during the closing delay of the circuit breaker from the measured slip frequency. The output is given only when all the measured conditions are within their set limits simultaneously. The issue of the output is timed to give closure at the optimal delay of the circuit breaker and the closing circuit.

### 5.3.4 Operation principle

The function can be enabled and disabled with the *Operation* setting. The corresponding parameter values are “On” and “Off”.

The synch-check function has two parallel functionalities, the synch-check and energizing check functionality. The operation of the synchronism and energizing check function can be described using a module diagram. All the modules in the diagram are explained in the next sections.

![Figure 167: Functional module diagram](image)

The synch-check function can operate either with V_AB or V_A voltages. The selection of used voltages is defined with the *VT connection* setting of the line voltage general parameters.
Energizing check

The energizing check function checks the energizing direction. Energizing is defined as a situation where a dead network part is connected to an energized section of the network. The conditions of the network sections to be controlled by the circuit breaker, that is, which side has to be live and which side dead, are determined by the setting. A situation where both sides are dead is possible as well. The actual value for defining the dead line or bus is given with the Dead bus value and Dead line value settings. Similarly, the actual values of live line or bus are defined with the Live bus value and Live line value settings.

</tr>
</tbody>
</table>

When the energizing direction corresponds to the settings, the situation has to be constant for a time set with the Energizing time setting, before the circuit breaker closing is permitted. The purpose of this time delay is to make sure that the dead side remains de-energized and also that the situation is not caused by a temporary interference. If the conditions do not persist for a specified operate time, timer is reset and the procedure is restarted when the conditions allow again. The circuit breaker closing is not permitted, if the measured voltage on the live side is greater than the set value of Max energizing V.

The measured energized state is available as monitored data value ENERG_STATE and as four function outputs LLDB (live line / dead bus), LLLB (live line / live bus), DLLB (dead line / live bus) and DLDB (dead line / dead bus) of which only one can be active at a time. It is also possible that the measured energized state indicates “Unknown”, if at least one of the measured voltages is between the limits set with the dead and live settings parameters.

In synch-check function the two voltage inputs are referred to as Bus and Line while in RER620 the inputs are referred to as Source-1 and Source-2. Unless otherwise indicated consider Source-1 as Bus and Source-2 as Line side. For example if Source 2 voltage goes below the ‘dead’ threshold setting, the same will be considered as Line Dead as TRUE by synchro-check function. If Source 2 voltage goes above ‘live’ threshold, the Live Line will be TRUE

Synch-check

The synch-check function measures the difference between the line voltage and bus voltage. The function permits the closing of the circuit breaker when the following conditions are simultaneously fulfilled.
• The measured line and bus voltages are higher than set values of Live bus value and Live line value (ENERG_STATE equals to “Both Live”).
• The measured bus and line frequency are both within the range of 95 to 105 percent of the value of $f_n$.
• The measured voltages for the line and bus are less than set value of Max energizing $V$.

In case Synch check mode is set to “Synchronous”, the additional conditions must be fulfilled:

• In the synchronous mode, the closing is attempted so that the phase difference at closing is close to zero.
• The synchronous mode is only possible when the frequency slip is below 0.1 percent of the value of $f_n$.
• The voltage difference must not exceed the 1 percent of the value of $VV_n$.

In case Synch check mode is set to “Asynchronous”, the additional conditions must be fulfilled:

• The measured difference of the voltages is less than the set value of Difference voltage.
• The measured difference of the phase angles is less than the set value of Difference angle.
• The measured difference in frequency is less than the set value of Frequency difference.
• The estimated breaker closing angle is decided to be less than the set value of Difference angle.

Figure 168: Conditions to be fulfilled when detecting synchronism between systems

When the frequency, phase angle and voltage conditions are fulfilled, the duration of the synchronism conditions is checked so as to ensure that they are still met when the condition is determined on the basis of the measured frequency and phase difference. Depending on the circuit breaker and the closing system, the delay from the moment the closing signal is given until the circuit breaker finally closes is about 50 - 250 ms. The selected Closing time of CB informs the function how long, the conditions have to persist. The synch-check function compensates for the measured slip frequency and the circuit
breaker closing delay. The phase angle advance is calculated continuously with the formula:

\[
\phi_{\text{V,BUS}} \quad \text{Measured bus voltage phase angle} \\
\phi_{\text{V,LINEN}} \quad \text{Measured line voltage phase angle} \\
f_{\text{V,BUS}} \quad \text{Measured bus frequency} \\
f_{\text{V,LINEN}} \quad \text{Measured line frequency} \\
T_{\text{CB}} \quad \text{Total circuit breaker closing delay, including the delay of the relay output contacts defined with the Closing time of CB setting parameter value}
\]

The closing angle is the estimated angle difference after the breaker closing delay. The *Minimum Syn time* setting time can be set, if required, to demand the minimum time within which conditions must be simultaneously fulfilled before the *SYNC_OK* output is activated.

The measured voltage, frequency and phase angle difference values between the two sides of the circuit breaker are available as monitored data values *V_DIFF_MEAS*, *FR_DIFF_MEAS* and *PH_DIFF_MEAS*. Also, the indications of the conditions that are not fulfilled and thus preventing the breaker closing permission, are available as monitored data values *V_DIFF_SYNC*, *PH_DIF_SYNC* and *FR_DIFF_SYNC*. These monitored data values are updated only when the synch-check enabled with the *Synch check mode* setting and the measured *ENERG_STATE* is “Both Live”.

**Continuous mode**

The synch-check functionality can be selected with the *Control mode* setting. The “Continuous” mode can be used for two different operating conditions, the most typical of which is where both sides of the circuit breaker to be closed are live. The synchronism is always checked before the circuit breaker is given the permission to close. The other situation is where one or both sides of the circuit breaker to be closed are dead and, consequently, the frequency and phase difference cannot be measured. In this case, the function checks the energizing direction. The user is able to define the voltage range within which the measured voltage is determined to be “live” or “dead”.

The continuous control mode is selected with the *Control mode* setting. In the continuous control mode, the synch-check is continuously checking the synchronism. When the synchronism conditions or the energizing check conditions are fulfilled, the *SYNC_OK* output is activated and it remains activated as long as the conditions remain fulfilled. The command input is ignored in the continuous control mode. The mode is used for situations where the synch-check only gives the permission to the control block that executes the CB closing.
Command mode

If Control mode is set to “Command”, the purpose of the synch-check functionality in the command mode is to find the instant when the voltages on both sides of the circuit breaker are in synchronism. The conditions for synchronism are met when the voltages on both sides of the circuit breaker have the same frequency and are in phase with a magnitude that makes the concerned busbars or lines can be regarded as live.

In the command control mode operation, an external command signal CL_COMMAND, besides the normal closing conditions, is needed for delivering the closing signal. In the command control mode operation, the synch-check function itself closes the breaker via the SYNC_OK output when the conditions are fulfilled. In this case, the control function block delivers the command signal to close the synch-check function for the releasing of a closing signal pulse to the circuit breaker. If the closing conditions are fulfilled during a permitted check time set with Maximum Syn time, after the command signal is delivered for closing, the synch-check function delivers a closing signal to the circuit breaker.

The closing signal is delivered only once for each activated external closing command signal. The pulse length of the delivered closing is set with the Close pulse setting.
In the command control mode operation, there are alarms for a failed closing attempt (CL_FAIL_AL) and for a command signal that remains active too long (CMD_FAIL_AL).

If the conditions for closing are not fulfilled within set time of Maximum Syn time, a failed closing attempt alarm is given. The CL_FAIL_AL alarm output signal is pulse shaped and the pulse length is 500 ms. If the external command signal is removed too early, that is, before conditions are fulfilled and close pulse is given, the alarm timer is reset.

The control module receives information about the circuit breaker status and thus is able to adjust the command signal to be delivered to the synch-check function. If the external command signal CL_COMMAND is kept active longer than necessary, CMD_FAIL_AL alarm output is activated. The alarm indicates that the control module has not removed the external command signal after the closing operation. To avoid unnecessary alarms, the duration of the command signal should be set in such a way that the maximum length of the signal is always below Maximum Syn time + 5s.
Figure 173: Determination of the alarm limit for a still-active command signal

Closing is permitted during Maximum Syn time, starting from the moment the external command signal \texttt{CL\_COMMAND} is activated. The \texttt{CL\_COMMAND} input must be kept active for the whole time that the closing conditions are waited to be fulfilled. Otherwise, the procedure is cancelled. If the closing command conditions are fulfilled during Maximum Syn time, a closing pulse is delivered to the circuit breaker. If the closing conditions are not fulfilled during the checking time, the alarm \texttt{CL\_FAIL\_AL} is activated as an indication of a failed closing attempt. The closing pulse is not delivered if the closing conditions become valid after Maximum Syn time has elapsed. The closing pulse is delivered only once for each activated external command signal and new closing command sequence cannot be started until the external command signal is reset and then activated again. The \texttt{SYNC\_INPRO} output is active when the closing command sequence is in progress and it is reset when the \texttt{CL\_COMMAND} input is reset or Maximum Syn time has elapsed.

### Bypass mode

SECRSYN can be set into bypass mode by setting the parameters Synch check mode and Energizing check mode to “Off” or alternatively, by activating the \texttt{BYPASS} input.

In bypass mode, the closing conditions are always considered to be fulfilled by the SECRSYN function. Otherwise, the operation is similar to the normal mode.

### Voltage angle difference adjustment

In application where the power transformer is located between the voltage measurement and the vector group connection gives phase difference to the voltages between the high and low-voltage sides, the angle adjustment can be used to meet synchronism.
The vector group of the power transformer is defined with clock numbers, where the value of the hour pointer defines the low voltage-side phasor and the high voltage-side phasor is always fixed to the clock number 12 which is same as zero. The angle between clock numbers is 30 degrees. When comparing phase angles, the $V_{BUS}$ input is always the reference. This means that when the Yd11 power transformer is used, the low voltage-side voltage phasor leads by 30 degrees or lags by 330 degrees the high voltage-side phasor. The rotation of the phasors is counterclockwise.

The generic rule is that a low voltage-side phasor lags the high voltage-side phasor by clock number $\times 30^\circ$. This is called angle difference adjustment and can be set for the function with the Phase shift setting.

### 5.3.5 Application

The main purpose of the synch-check function is to provide control over the closing of the circuit breakers in power networks to prevent the closing if the conditions for synchronism are not detected. This function is also used to prevent the reconnection of two systems which are divided after islanding and a three-pole reclosing.

The synch-check function block includes both the synchronism check function and the energizing function to allow closing when one side of the breaker is dead.
Network and the generator running in parallel with the network are connected through the line AB. When a fault occurs between A and B, the relay protection opens the circuit breakers A and B, thus isolating the faulty section from the network and making the arc that caused the fault extinguish. The first attempt to recover is a delayed autoreclosure made a few seconds later. Then, the autoreclose function SDARREC gives a command signal to the synch-check function to close the circuit breaker A. SECRSYN performs an energizing check, as the line AB is de-energized ($V_{BUS}$ > Live bus value, $V_{LINE}$ < Dead line value). After verifying the line AB is dead and the energizing direction is correct, the relay energizes the line ($V_{BUS}$ -> $V_{LINE}$) by closing the circuit breaker A. The PLC of the power plant discovers that the line has been energized and sends a signal to the other synch-check function to close the circuit breaker B. Since both sides of the circuit breaker B are live ($V_{BUS}$ > Live bus value, $V_{LINE}$ > Live bus value), the synch-check function controlling the circuit breaker B performs a synch-check and, if the network and the generator are in synchronism, closes the circuit breaker.

![Figure 175: Synch-check function SECRSYN checking energizing conditions and synchronism](image)

**Connections**

A special attention is paid to the connection of the relay. Further, it is checked that the primary side wiring is correct.

A faulty wiring of the voltage inputs of the relay causes a malfunction in the synch-check function. If the wires of an energizing input have changed places, the polarity of the input voltage is reversed (180°). In this case, the relay permits the circuit breaker closing in a situation where the voltages are in opposite phases. This can damage the electrical devices in the primary circuit. Therefore, it is extremely important that the wiring from the voltage transformers to the terminals on the rear of the relay is consistent regarding the energizing inputs $V_{BUS}$ (bus voltage) and $V_{LINE}$ (line voltage).

The wiring should be verified by checking the reading of the phase difference measured between the $V_{BUS}$ and $V_{LINE}$ voltages. The phase difference measured by the relay has to be close to zero within the permitted accuracy tolerances. The measured phase
differences are indicated in the LHMI. At the same time, it is recommended to check the voltage difference and the frequency differences presented in the Monitored data view. These values should be within the permitted tolerances, that is, close to zero.

Figure 176 shows an example where the synch-check is used for the circuit breaker closing between a busbar and a line. The phase-to-phase voltages are measured from the busbar and also one phase-to-phase voltage from the line is measured.

5.4.2 Function block

![Figure 177: Function block]

5.4.3 Functionality

The loop control functionality enables proper switching of recloser in order to sectionalize the faulted section from the distribution system. The function can be operated in three modes, based on the type of the recloser in the loop control scheme. The full scheme of loop control typically consists of three types of recloser used in the loop control system design. They are sectionalizer recloser, mid-point recloser and tie-point recloser. The functionality of loop control function in different modes is clearly explained in the next sections of the document.
A recloser loop control scheme typically utilizes a predetermined RER620 controlled reclosers installed in series between two substation feeder circuits. This provides isolation of any faulted section within a given distribution circuit while re-establishing service to all customers unaffected by the faulted section within a relatively short period. Loop control schemes are typically located at or near key customers at various locations throughout the distribution system, or where reliability on particular circuits is particularly poor.

There are three common configurations that the loop control can be configured. These are defined by the number of reclosers in a loop and their respective types. The three- and five recloser systems are basic arrangements; the four-recloser topology is a hybrid of the three- and five-recloser topology.

The distribution one-line diagram in Figure 178 represents a typical full implementation of a loop system.

**Figure 178:** 5-Recloser loop control system

A typical full implementation of a loop system consists of 3 type of reclosers:

- Sectionalizing reclosers
- Midpoint reclosers
- TiePoint recloser

An explanation of the function of each of these reclosers types is given in the section below.

### 5.4.3.1 Sectionalizing Recloser

The Sectionalizing recloser is a normally closed recloser that opens in response to a downstream fault condition or to a loss of phase voltage from an upstream circuit. The sectionalizer is typically the first protective device on the distribution line outside the substation. Various settings determine the Sectionalizing recloser's sensitivity to both current and voltage conditions. By design, for permanent faults between the substation and
the Sectionalizing recloser, the Sectionalizing recloser will open after a program delay to set up for the back feeding from the alternate source. This timer is set to expire prior to the Midpoint and Tiepoint timers.

5.4.3.2  
Midpoint Recloser

The Midpoint recloser also is normally closed. Unlike the Sectionalizing recloser, however, it does not open in response to phase voltage loss. Instead, it supports loop control by automatically altering the RER620 settings in accordance with changing voltage conditions. Specifically, upon the expiration of its under voltage timer, it will switch to a new setting group to prepare for a back feed condition and for a period will go into non-reclose mode. The reason for the non-reclose is that in the event the fault is between the Sectionalizing unit and the Midpoint, it would be undesirable to have the recloser sequence through multiple operations. Though the reclose blocked condition will change to normal after a programmed amount of time, the control will stay in New Settings Group until the loop scheme is reset.

5.4.3.3  
Tiepoint Recloser

The Tiepoint recloser, unlike the Sectionalizing and Midpoint recloser is normally open. It closes in response to a loss of all phase voltages from one source if the other source phase voltages are live. Once closed, the Tiepoint breaker will trip automatically if a downstream overcurrent condition exists and is not isolated by the midpoint recloser first. The Tiepoint recloser can be set to employ different fault thresholds depending on which side of the loop it is supplying, i.e., which side is downstream. After the close operation, it also is set to go into non-reclose mode for a period of time in the event the fault is between the Midpoint and Tiepoint. If the control changed to New Settings Group for the close operation, it will remain in that setting group until the Recloser is opened and the loop scheme is reset.

5.4.4  
Operation principle

The Operation setting is used to enable or disable the function. When selected “On” the function is enabled and respectively “Off” means function is disabled.

The operation of DLCM can be described by using a module diagram (see Figure 179). All the modules in the diagram are explained in the next sections.
Phase selection

The identification of source and phases for which, phase status has to be determined is done in the phase selection.

A source is a substation feeder with breaker and ancillary equipment. The substation source is not normally included in the loop scheme logic system, it is only intended to supply the power for the loop control system down the feeder. All loop control systems assume two sources of supply. These sources may be supplied by the same or different distribution substation feeders, with different feeders permitting a higher level of service during some fault conditions. The selection of these substations it is recommended that the following be considered:

- Both sources supply power of the same phase rotation
- The voltage level of each source are similar
- The capacity of the each source/feeder (transformers, protective devices, regulators, wire, etc. are capable of picking up load of the feeder to be added by a loop operation (normally to the Sectionalizing recloser on the other source).

The phase selection is done based on the below listed settings.

- Line side src
- Vt config line
- Vt line phase
- Vt line enable
- Vt config load
- Vt load phase
- Vt load enable

Basically the recloser consists of two bus voltages as S1 and S2. This is clearly depicted in Figure 180.
Independent of type of recloser in loop control scheme, i.e., either recloser is sectionalizing, mid-point or tie-point, the sources and phases will be similar to Figure 180.

The phase selection for the three modes is explained below.

The loop control is operated in 4 modes as “Sectionalize”, “Mid-point”, “Tie-point” or “Disabled” in LCM Mode setting.

The Line side src setting can be selected as “S1” or “S2” to select the respective source as line side source. If the power is flowing from S1 to S2 then the Line side src is selected as “S1” and vice versa. This is explained pictorially in Figure 181.

Once the line side source is selected the phases of the respective source is identified by giving the number of voltage transformers connected to the respective source.

In case of sectionalizer mode, the Vt config line setting is selected with number of voltage transformers connected. If the Vt config line is “1” or “2”, the Vt line phase setting is
selected as the phase to which the voltage transformers is connected. The *Vt line enable* should be TRUE to consider the settings *Vt config line* and *Vt line phase*. Table 311 clearly explains the phases selected with different possible selection of appropriate settings in Sectionalizing recloser modes.

In case of mid-point mode, the numbers of voltage transformers connected can be either 1 or 3. So the *Vt config line* can be either “1” or “3”. The phase selection is similar as in sectionalizer mode but *Vt config line* cannot be “2”.

In case of tie-point mode the 3 phases of both sources are considered. Hence in tie-point mode the *Vt config line* and *Vt config load* settings should be selected as “3” and *Vt line enable* and *Vt load enable* should be selected as ‘TRUE’. That is tie-point recloser should always have 3 voltage transformers connected to each source.

In case of disabled mode no phase is considered.

</tr>
</tbody>
</table>

The outputs S1_DISABLED and S2DISABLED indicate whether the respective source is enabled or disabled. The output will be TRUE if respective source is disabled.

The condition for any source to be enabled in sectionalizer or midpoint modes is the respective source should be selected as Line side source and *Vt line enable* should be “TRUE” and the respective source enable input should be triggered with a positive pulse.
The condition for any source to be enabled in tie-point mode is to set the settings Vt line enable and Vt load enable as TRUE and the respective source enable inputs should be triggered with a positive pulse.

The source enable inputs S1_ENABLE and S2_ENABLE are pulse triggered inputs. This is true if the present status of source is enabled. By applying a positive pulse to the respective inputs the respective source will be disabled and vice versa.

**Phase status determination**

Phase status determination module determines the status of phases selected. The status of phase can be live or dead or neither live nor dead based on the level of the respective phase voltages.

The phase status logic compares the measured value of the respective phase voltage with Live bus threshold and Dead bus threshold settings. If the measured voltage is greater than Live bus threshold for a time of Live bus time then the respective phase is declared as live bus. If the measured voltage is less than Dead bus threshold for a time of Dead bus time then respective phase is declared as dead bus. If the measured voltage exceeds the Dead bus threshold for a time less than Volt regain time then it is ignored by the function and dead bus timer will be continuous during this time. If the voltage is restored for the Volt regain time or longer, the dead bus timer is cleared and the status will change to either live bus or neither live nor dead based on the voltage level. The phase is declared as neither live nor dead if the phase voltage is above the Dead bus threshold and below the Live bus threshold.

In sectionalizing mode, if Vt config line is “3” and the setting Sect3POpMode is selected as “Any phase” then any of the 3 phases should be declared as dead to activate the LCM_TRIP. If Sect3POpMode is selected as “Three phase” then all of the 3 phases should be declared as dead to activate the LCM_TRIP. If Vt config line is “1” then the respective phase selected in Vt line phase setting should be declared as dead to activate the LCM_TRIP.

In midpoint mode, the SET_GROUP_CHANGE is activated and SWOTF output is activated for a time of SWOTF time setting if the status of the phases selected is dead and if En set grp chg setting is TRUE.

In tie point mode, the LCM_CLOSE is activated and also the SWOTF output is activated for a time of SWOTF time setting, if the status of the 3 phases of one source is live and the status of 3 phases of the other source is dead. And also the SET_GROUP_CHANGE is activated, if source selected as line side is dead and if En set grp chg setting is TRUE.

The S1_STATUS and S2_STATUS outputs, provides the status of the respective bus. If the output is activated, it indicates the respective source is dead and vice versa.

The binary input BLOCK can be used to block the function. The activation of the BLOCK input deactivates all outputs and resets internal timers.

**Reset Logic**

The loop control function is provided with reset logic for safety reasons. The reset logic is explained for each of the loop control modes in the next few paragraphs.
In the sectionalizer and midpoint mode, if the setting Reset on power up is set as "TRUE", then after any re-initialization activity in the relay like power off-and-on, software reset, committing to a setting change etc., the loop control will be in reset or active state and RESET_OUT output will be FALSE. If the setting Reset on power up is set as "FALSE", then after any re-initialization activity in the relay, the loop control will be in non-reset or in-active state and RESET_OUT output will be TRUE. In the later case, to arm the loop control, RESET_IN input is triggered with a positive pulse. The loop control goes into non–reset state if LCM_TRIP output is activated in sectionalizer mode or SET_GROUP_CHANGE output is activated in mid-point mode. After restoring the line, the loop control is reset by providing a positive pulse through RESET_IN input.

In the tie-point mode, after the power on and power off of relay, the loop control will always go into non–reset mode due to safety reasons. The loop control can be moved to active state by providing a positive pulse at RESET_IN input. The loop control goes into non–reset state if LCM_CLOSE output is activated. After restoring the line, the loop control is reset by providing a positive pulse through RESET_IN input.

The RESET_OUT indicates whether the loop control is in reset or non-reset state. If RESET_OUT is TRUE it indicated the loop control is in non reset state and vice versa.

</tr>
</tbody>
</table>

The sectionalizing reset setting provides automation on the reset logic in sectionalizing mode. If sectionalizing reset is TRUE then if the loop control is in non reset mode and if the bus voltage is above live bus threshold for live bus time then the loop control will go into reset mode automatically. This feature is only applicable in sectionalizing recloser mode.

**5.4.5 Application**

The loop control scheme is implemented to improve the circuit reliability and to provide more effective system operation. The loop control function is used in implementing the loop control schemes.
In general, loop control scheme is implemented in three different configurations. These are defined by the number of reclosers in a loop and their respective types. They are five recloser, three recloser and four recloser configurations. The three- and five recloser systems are basic arrangements; the four-recloser topology is a hybrid of the three- and five-recloser topology.

5.4.5.1 Three-Recloser Loop Control

The three-recloser system bridges two sources with a normally open TiePoint recloser. Between each source and the TiePoint is a normally closed sectionalizing recloser. There are two fault scenarios to consider in the three-recloser system. In one scenario, a line fault occurs between a source and its Sectionalizing recloser. The second scenario involves a line fault between the Sectionalizing and TiePoint recloser.

**Figure 182: 3-Recloser Loop Control**

3-Recloser Fault 1 Scenario

In a 3-recloser loop control scheme, Figure 182, if there is a permanent fault between the S1 circuit breaker and the sectionalizing recloser B at F1, the S1 circuit breaker will recognize the fault and go through its reclosing shots to lockout (for illustration purposes we will assume 3 operations to lockout for all devices). Recloser B will recognize a loss of voltage after the first circuit breaker operation, and if the voltage does not return to greater than live bus threshold value level for the livebus timer setting, it will automatically trip after t1 seconds, per Figure 183, isolating the faulted zone on the source side of the recloser. The tie-point recloser T at the same instant will recognize a loss of 3-phase voltage on the S1 side of its recloser PTs. After a delay time of t2 seconds from the initial fault at S1 the tie-point recloser T will close. This establishes service from S2, recloser A and through the tie-point recloser T to the faulted sectionalizing recloser B. Figure 183 and Table 313 summarize the events.
If a permanent fault occurred at location F2, Figure 182, the following sequence occurs:

B proceeds through its reclosing sequence of overcurrent protection, which is the primary protection activity for the RER620. Upon tripping of recloser B, recloser T senses loss of voltage and after its time delay of \( t_1 \) seconds, closes onto the permanent fault. Since this fault is permanent and recloser T has closed into the fault, recloser T goes directly to lockout by design. The unfaulted portion of the distribution feeder circuit between S1 to recloser B remains in service, as does S2 to recloser T. Figure 184 and Figure 314 summarize the sequence of events.
Loop Schemes can be setup as one-way or two-way systems. One-way systems allow the tiepoint recloser close when voltage is lost on one side but not the other. This may be necessary for situations where the one feeder cannot support additional load but can be picked up by the other feeder. Two-way schemes are more common, and are set to pick up load in either direction. For two-way schemes, there may be a need for an alternate protection setting group change for proper coordination. This can be done automatically based on programmed settings.

5.4.5.2 Five-Recloser Loop Control

The five-recloser system is similar to the three-recloser system except that a normally closed Midpoint recloser divides the segments between the TiePoint recloser and each Sectionalizing recloser. Figure 185 shows the relative location of midpoint reclosers. The Mid-point recloser differs from Sectionalizing and TiePoint reclosers in that it does not initiate breaker operations (trip or close) based on phase voltages. Instead, it alters the RER620's response to overcurrent conditions. Upon a loss of voltage (below dead bus threshold voltage level) and after the programmed Dead bus time, the Midpoint RER620 will activate have two additional outputs, which include:

- Switch-on-to-fault (SWOTF)
- SET_GROUP_CHANGE

If the status of phases selected is dead, the SET_GROUP_CHANGE is activated if "En Set Grp chg" setting is TRUE and SWOTF output is activated for time of SWOTF time setting preventing the recloser from reclosing back into an anticipated fault for a back feed condition (after the tie-point closes).
Once the SWOTF timer expires, the unit goes into normal reclosing mode to allow isolation of any subsequent temporary faults.

Note that the Tie-point loop control mode also enables SWOTF output for a time of SWOTF time setting if the status of the 3 phases of one source is live and the status of 3 phases of the other source is dead. And also the SET_GROUP_CHANGE is activated, if source selected as line side is dead and if "En set grp chg" setting is TRUE.

SET_GROUP_CHANGE settings refer to alternate current thresholds used by the RER620 in recognizing overcurrent conditions. This is important in the Midpoint and TiePoint reclosers because their loads and protective settings may vary depending on which source is supplying the power. The user can optionally program both the Midpoint and TiePoint reclosers to switch to another group settings when initiating loop control sequences.

Because of the additional reclosers in a five-recloser system, there are three potential fault locations on each side of the TiePoint:

- Between source and Sectionalizing recloser
- Between Sectionalizing and Midpoint reclosers
- Between Midpoint and TiePoint reclosers

![Figure 185: 5-Recloser Loop Control](image)

### 5-Recloser Fault 1 Scenario

In a 5-recloser loop control scheme, Figure 185, if there is a permanent fault between the S1 circuit breaker and the sectionalizing recloser B at F1, the S1 circuit breaker will recognize the fault and go through its reclosing shots to lockout (for illustration purposes we will assume 3 operations to lockout for all devices). Recloser B will recognize a loss...
of voltage after the first circuit breaker operation, and if the voltage does not return for the livebus timer setting, it will automatically trip after \( t_1 \) seconds (see Figure 186), isolating the faulted zone on the source side of the recloser.

The Midpoint recloser C senses the same loss of voltage, and if the voltage does not return for the livebus timer setting will request the RER620 to start its SWOTF timer and, if programmed, to use new changed group settings after \( t_2 \) seconds (typically set around 10 seconds after the Sectionalizer is set to lockout).

The tie-point recloser T at the same instant will recognize a loss of 3-phase voltage on the S1 side of its recloser PTs. After a delay time of \( t_3 \) seconds from the initial fault at S1 the tie-point recloser T will close, and if programmed, switch to New Group settings. This establishes service from S2, recloser A and through the tie-point recloser T to the faulted sectionalizing recloser B. The TiePoint recloser is typically set to declare its phase voltages dead sometime after the Midpoint recloser has started its SWOTF timer and before the SWOTF timer expires.

The unfaulted portion of the distribution feeder circuit between recloser B and recloser T is picked back up. Figure 186 and Table 315 summarize the events.

**Figure 186:** 5-Recloser Fault 1 scenario Sequence of Events

</tr>
</tbody>
</table>

**Table 315:** 5-Recloser Fault 1 scenario Sequence of Events

5-Recloser Fault 2 Scenario

In a 5-recloser loop control scheme, Figure 182, if there is a permanent fault between the sectionalizing recloser B and the midpoint recloser C at F2, recloser B will recognize the fault and go through its reclosing shots to lockout (assuming proper coordination with the circuit breaker at Source 1). Recloser C will recognize a loss of voltage after the first
recloser B operation, and if the voltage does not return for the livebus timer setting, will request the RER620 to start its SWOTF timer and, if programmed, to use New Group Settings after t2 seconds (typically set around 10 seconds after the Sectionalizer is set to trip). See Figure 187 the tie-point recloser T at the same instant will recognize a loss of 3-phase voltage on the S1 side of its recloser PTs. After a delay time of t3 seconds from the initial fault at S1 the tie-point recloser T will close, and if programmed, switch to New Group Settings. Since the fault is permanent, fault current will flow from the alternate source. With proper coordination in this direction, the mid-point recloser will trip on overcurrent (one shot due to its SWOTF mode), isolating the faulted section between Recloser B and C. This establishes service from S2 to Recloser C. The TiePoint recloser is typically set to declare its phase voltages dead sometime after the Midpoint recloser has started its SWOTF timer and before the SWOTF timer expires. The unfaulted portion of the distribution feeder circuit from S2 to recloser B never loses service, and from Recloser C to the tie-point recloser the load is picked back up. Figure 187 and Table 316 summarize the events.

**Figure 187: 5-Recloser Fault 2 scenario Sequence of Events**

**Table 316: 5-Recloser Fault 2 scenario Sequence of Events**

<table>
<thead>
<tr>

</tr>
<tr>
<td>t2</td>
<td>TiePoint recloser declares phases dead, initiates loop control sequence and closes its breaker. May request ALT thresholds (per settings) before closing breaker.</td>
</tr>
</tbody>
</table>

**5-Recloser Fault 3 Scenario**

If a permanent fault occurred at location F3, Figure 186, the following sequence occurs; recloser C proceeds through its reclosing sequence of overcurrent protection (assume 3 operations to lockout). Upon tripping of recloser C, recloser T senses loss of voltage and after its time delay of t1 seconds, closes onto the permanent fault. Since this fault is permanent and recloser T has closed into the fault, recloser T does not go through the same recloser sequence as recloser C just went through, recloser T goes directly to lockout. The unfaulted portion of the distribution feeder circuit between S1 to recloser C remains in
service, as does S2 to recloser T. Figure 188 and Table 317 summarize the sequence of events.

**Figure 188:** 5-Reclose Fault 3 scenario Sequence of Events

### 5.4.5.3 Four-Recloser System Operation

A four-recloser system is a hybrid of the three- and five-recloser systems. Between one source and the TiePoint, recloser is a Sectionalizing recloser and a Midpoint recloser. Only a Sectionalizing recloser appears between the other source and the TiePoint. The Sectionalizer and Midpoint from one source of the TiePoint is configured like reclosers in a five-recloser system. The other Sectionalizing recloser is configured like its counterpart in a three-recloser system. TiePoint configuration and operation is similar in all three topologies.

### 5.4.5.4 Restoring Normal Operation

The "Reset Logic" section covered previously explains on the steps involved in resetting the LCM function and activated again safely when reclosers working in different modes. All the restoration steps should be performed before in full compliance with all applicable safety procedures before resetting the LCM functionality in RER620 relay.

5.5.2 Function block

![Function block diagram]

*Figure 189: Function block*

5.5.3 Functionality

The generic up-down counter function UDFCNT counts up or down for each positive edge of the corresponding inputs. The counter value output can be reset to zero or pre-set to some other value, if required.

The UDFCNT function provides up-count and down-count status outputs, which specify the relation of the counter value to a loaded preset value and to zero respectively.

5.5.4 Operation principle

The Operation setting is used to enable or disable the function. When selected "On" the function is enabled and respectively "Off" means the function is disabled.

The operation of UDFCNT can be described by using a module diagram (see Figure 190).
Section 5  
Control functions

Figure 190: Functional module diagram

Up-down counter

Each rising edge of the UP_CNT input increments the counter value CNT_VAL by one and each rising edge of the DOWN_CNT input decrements the CNT_VAL by one. If there is a rising edge at both the inputs UP_CNT and DOWN_CNT, then the counter value CNT_VAL is unchanged. The CNT_VAL is available through the Monitored data view.

The counter value CNT_VAL is stored in a non-volatile memory. The range of the counter is 0...+2147483647. The count of CNT_VAL saturates at the final value of 2147483647, that is, no further increment is possible.

The value of the setting Counter load value is loaded into counter value CNT_VAL either when the LOAD input is set to TRUE or when the Load Counter is set to “Load” in the LHMI. Till the LOAD input is TRUE, it prevents all further counting.

The function also provides status outputs UPCNT_STS and DNCNT_STS. The UPCNT_STS is set to TRUE when the CNT_VAL is greater than or equal to setting Counter load value. DNCNT_STS is set to TRUE when the CNT_VAL is equal to zero.

The RESET input is used for resetting of the function. When this input is set to TRUE or when the Reset counter is set to “reset” the CNT_VAL is forced to zero.

<td>52CM</td>
</tr>
</tbody>
</table>

6.1.2  Function block

![Figure 191: Function block](image)

6.1.3  Functionality

The circuit breaker condition monitoring function 52CM is used to monitor different parameters of the circuit breaker. The breaker requires maintenance when the number of operations has reached a predefined value. For proper functioning of the circuit breaker, it is essential to monitor the circuit breaker operation, spring charge indication, breaker wear, travel time, number of operation cycles and accumulated energy. The energy is calculated from the measured input currents as a sum of $I^2t$ values. Alarms are generated when the calculated values exceed the threshold settings.

The function contains a blocking functionality. It is possible to block the function outputs, if desired.
6.1.4 Operation principle

The circuit breaker condition monitoring function includes different metering and monitoring subfunctions. The functions can be enabled and disabled with the Operation setting. The corresponding parameter values are Enable and Disable. The operation counters are cleared when Operation is set to Disable.

The operation of the functions can be described by using a module diagram. All the modules in the diagram are explained in the next sections.
Figure 192: Functional module diagram
### 6.1.4.1 Circuit breaker status

The circuit breaker status subfunction monitors the position of the circuit breaker, that is, whether the breaker is in an open, closed or intermediate position. The operation of the breaker status monitoring can be described by using a module diagram. All the modules in the diagram are explained in the next sections.

![Diagram of circuit breaker status](image)

**Figure 193:** Functional module diagram for monitoring circuit breaker status (Typical pole, shown for Phase A)

#### Phase current check

This module compares the three phase currents with the setting *ACC stop current*. If the current in a phase exceeds the set level, information about phase is reported to the contact position indicator module.

#### Contact position indicator

The circuit breaker status is open if the auxiliary input contact `POSCLOSE_A(_B, _C)` is low, the `POPCLOSE_A(_B, _C)` input is high and the current is zero. The circuit breaker is closed when the `POPCLOSE_A(_B, _C)` input is low and the `POSCLOSE_A(_B, _C)` input is high. The breaker is in the intermediate position if both the auxiliary contacts have the same value, that is, both are in the logical level “0”, or if the auxiliary input contact `POSCLOSE_A(_B, _C)` is low and the `POPCLOSE_A(_B, _C)` input is high, but the current is not zero.

The status of the breaker is indicated with the binary outputs `OPENPOS_A(_B, _C)`, `INVALIDPOS_A(_B, _C)`, and `CLOSEPOS_A(_B, _C)` for open, intermediate, and closed position respectively.

### 6.1.4.2 Circuit breaker operation monitoring

The purpose of the circuit breaker operation monitoring subfunction is to indicate if the circuit breaker has not been operated for a long time.

This subfunction requires two position inputs `POSCLOSE_A(_B, _C)` and `POPCLOSE_A(_B, _C)` from the circuit breaker.

The operation of the circuit breaker operation monitoring can be described by using a module diagram. All the modules in the diagram are explained in the next sections.
Inactivity timer

The module calculates the number of days the circuit breaker has remained inactive, that is, has stayed in the same open or closed state. The calculation is done by monitoring the states of the $\text{POSOPEN}_A(_B, _C)$ and $\text{POSCLOSE}$ auxiliary contacts.

The inactive days is available through the Monitored data view. It is also possible to set the initial inactive days by using the parameter.

Alarm limit check

When the inactive days exceed the limit value defined with the setting, the alarm is initiated. The time in hours at which this alarm is activated can be set with the parameter as coordinates of UTC. The alarm signal can be blocked by activating the binary input $\text{BLOCK}$.

6.1.4.3 Breaker contact travel time

The breaker contact travel time module calculates the breaker contact travel time for the closing and opening operation. The operation of the breaker contact travel time measurement can be described by using a module diagram. All the modules in the diagram are explained in the next sections.

This subfunction requires two position inputs $\text{POSOPEN}_A(_B, _C)$ and $\text{POSCLOSE}_A(_B, _C)$ from the circuit breaker.
Condition monitoring functions

Traveling time calculator

The contact travel time of the breaker is calculated from the time between auxiliary contacts’ state change. The open travel time is measured between the opening of the POSCLOSE_A(_B, _C) auxiliary contact and the closing of the POSOPEN_A(_B, _C) auxiliary contact. Travel time is also measured between the opening of the POSOPEN auxiliary contact and the closing of the POSCLOSE_A(_B, _C) auxiliary contact.

![Functional module diagram for breaker contact travel time](image)

**Figure 195:** Functional module diagram for breaker contact travel time

There is a time difference $t_1$ between the start of the main contact opening and the opening of the POSCLOSE_A(_B, _C) auxiliary contact. Similarly, there is a time gap $t_2$ between the time when the POSOPEN_A(_B, _C) auxiliary contact opens and the main contact is completely open. Therefore, in order to incorporate the time $t_1+t_2$, a correction factor needs to be added with $t_{open}$ to get the actual opening time. This factor is added with the

**Figure 196:** Travel time calculation

$T_{TRV\_OP\_A} = t_{open} + t_1 + t_2$

$T_{TRV\_CL\_A} = t_{close} + t_3 + t_4$
Opening time Cor \( (t_1 + t_2) \). The closing time is calculated by adding the value set with the Closing time Cor \( (t_3 + t_4) \) setting to the measured closing time.

The last measured opening travel time \( T_{TRV\_OP\_A\(_B\_,\_C\)} \) and the closing travel time \( T_{TRV\_CL\_A\(_B\_,\_C\)} \) are available through the Monitored data view on the LHMI or through tools via communications.

### Alarm limit check

When the measured open travel time is longer than the value set with the Open alarm time setting, the \( TRV\_T\_OP\_ALM \) output is activated. Respectively, when the measured close travel time is longer than the value set with the Close alarm time setting, the \( TRV\_T\_CL\_ALM \) output is activated.

It is also possible to block the \( TRV\_T\_CL\_ALM \) and \( TRV\_T\_OP\_ALM \) alarm signals by activating the BLOCK input.

### 6.1.4.4 Operation counter

The operation counter subfunction calculates the number of breaker operation cycles. Both open and close operations are included in one operation cycle. The operation counter value is updated after each open operation.

The operation of the subfunction can be described by using a module diagram. All the modules in the diagram are explained in the next sections.

**Figure 197:** Functional module diagram for counting circuit breaker operations

**Operation counter**
The operation counter counts the number of operations based on the state change of the binary auxiliary contacts inputs \texttt{POSCLOSE\_A(\_B,\_C)} and \texttt{POSO\_OPEN\_A(\_B,\_C)}.

The number of operations \texttt{NO\_OPR} is available through the Monitored data view on the LHMI or through tools via communications. The old circuit breaker operation counter value can be taken into use by writing the value to the parameter and in the clear menu from WHMI or LHMI.

**Alarm limit check**

The operation alarm is generated when the number of operations exceeds the value set with the threshold setting. However, if the number of operations increases further and exceeds the limit value set with the setting, the output is activated.

The binary outputs are and are deactivated when the \texttt{BLOCK} input is activated.

**6.1.4.5 Accumulation of I\textsuperscript{t}**

Accumulation of the I\textsuperscript{t} module calculates the accumulated energy.

The operation of the module can be described by using a module diagram. All the modules in the diagram are explained in the next sections.

![Figure 198: Functional module diagram for calculating accumulative energy and alarm](image)

**Accumulated energy calculator**

This module calculates the accumulated energy I\textsuperscript{t}. The factor $y$ is set with the Current exponent setting.

The calculation is initiated with the \texttt{POSCLOSE\_A(\_B,\_C)} input open events. It ends when the RMS current becomes lower than the Acc stop current setting value.
The Difference Cor time setting is used instead of the auxiliary contact to accumulate the energy from the time the main contact opens. If the setting is positive, the calculation of energy starts after the auxiliary contact has opened and when the delay is equal to the value set with the Difference Cor time setting. When the setting is negative, the calculation starts in advance by the correction time before the auxiliary contact opens.

The accumulated energy outputs IPOW_A(_B, _C) are available through the Monitored data view on the LHMI or through tools via communications. The values can be reset by setting the parameter CBCMx acc. energy setting to true in the clear menu from WHMI or LHMI.

**Alarm limit check**

The IPOW_ALM alarm is activated when the accumulated energy exceeds the value set with the Alm Acc currents Pwr threshold setting. However, when the energy exceeds the limit value set with the LO Acc currents Pwr threshold setting, the IPOW_LO output is activated.

The IPOW_ALM and IPOW_LO outputs can be blocked by activating the binary input BLOCK.

**6.1.4.6 Remaining life of the circuit breaker**

Every time the breaker operates, the life of the circuit breaker reduces due to wearing. The wearing in the breaker depends on the tripping current, and the remaining life of the breaker is estimated from the circuit breaker trip curve provided by the manufacturer. The remaining life is decremented at least with one when the circuit breaker is opened.

The operation of the remaining life of the circuit breaker subfunction can be described by using a module diagram. All the modules in the diagram are explained in the next sections.
Figure 200: Functional module diagram for estimating the life of the circuit breaker

**Circuit breaker life estimator**

The circuit breaker life estimator module calculates the remaining life of the circuit breaker. If the tripping current is less than the rated operating current set with the Rated Op current setting, the remaining operation of the breaker reduces by one operation. If the tripping current is more than the rated fault current set with the Rated fault current setting, the possible operations are zero. The remaining life of the tripping current in between these two values is calculated based on the trip curve given by the manufacturer. The Op number rated and Op number fault parameters set the number of operations the breaker can perform at the rated current and at the rated fault current, respectively.

The remaining life is calculated separately for all three phases and it is available as a monitored data value CB_LIFE_A (_B, _C). The values can be cleared by setting the parameter CB wear values in the clear menu from WHMI or LHMI.

Clearing CB wear values also resets the operation counter.

**Alarm limit check**

When the remaining life of any phase drops below the Life alarm level threshold setting, the corresponding circuit breaker life alarm CB_LIFE_ALM is activated.

It is possible to deactivate the CB_LIFE_ALM alarm signal by activating the binary input BLOCK. The old circuit breaker operation counter value can be taken into use by writing the value to the Initial CB Rmn life A(B, C) parameter and resetting the value via the clear menu from WHMI or LHMI under the Clear CB wear values menu.
6.1.4.7 Circuit breaker spring charged indication

The circuit breaker spring charged indication subfunction calculates the spring charging time.

This subfunction is not applicable to magnetic actuators.

The operation of the subfunction can be described by using a module diagram. All the modules in the diagram are explained in the next sections.

![Figure 201: Functional module diagram for circuit breaker spring charged indication and alarm](image)

Spring charge time measurement

Two binary inputs, SPR_CHR_ST and SPR_CHR, indicate spring charging started and spring charged, respectively. The spring charging time is calculated from the difference of these two signal timings.

The spring charging time $T_{SPR\_CHR}$ is available through the Monitored data view on the LHMI or through tools via communications.

Alarm limit check

If the time taken by the spring to charge is more than the value set with the Spring charge time setting, the subfunction generates the SPR_CHR_ALM alarm.

It is possible to block the SPR_CHR_ALM alarm signal by activating the BLOCK binary input.

6.1.4.8 Gas pressure supervision

The gas pressure supervision subfunction monitors the gas pressure inside the arc chamber.

This subfunction is not applicable to vacuum interruption.

The operation of the subfunction can be described by using a module diagram. All the modules in the diagram are explained in the next sections.
Condition monitoring functions

Figure 202: Functional module diagram for circuit breaker gas pressure alarm

The gas pressure is monitored through the binary input signals PRES_LO_IN and PRES_ALM_IN.

Timer 1

When the PRES_ALM_IN binary input is activated, the PRES_ALM alarm is activated after a time delay set with the Pressure alarm time setting. The PRES_ALM alarm can be blocked by activating the BLOCK input.

Timer 2

If the pressure drops further to a very low level, the PRES_LO_IN binary input becomes high, activating the lockout alarm PRES_LO after a time delay set with the Pres lockout time setting. The PRES_LO alarm can be blocked by activating the BLOCK input.

6.1.5 Application

52CM includes different metering and monitoring subfunctions.

Circuit breaker status

Circuit breaker status monitors the position of the circuit breaker, that is, whether the breaker is in an open, closed or intermediate position.

Circuit breaker operation monitoring

The purpose of the circuit breaker operation monitoring is to indicate that the circuit breaker has not been operated for a long time. The function calculates the number of days the circuit breaker has remained inactive, that is, has stayed in the same open or closed state. There is also the possibility to set an initial inactive day.

Breaker contact travel time

High travelling times indicate the need for maintenance of the circuit breaker mechanism. Therefore, detecting excessive travelling time is needed. During the opening cycle operation, the main contact starts opening. The auxiliary contact A opens, the auxiliary contact B closes, and the main contact reaches its opening position. During the closing cycle, the first main contact starts closing. The auxiliary contact B opens, the auxiliary contact A closes, and the main contact reaches its close position. The travel times are
calculated based on the state changes of the auxiliary contacts and the adding correction factor to consider the time difference of the main contact's and the auxiliary contact's position change.

**Operation counter**

Routine maintenance of the breaker, such as lubricating breaker mechanism, is generally based on a number of operations. A suitable threshold setting, to raise an alarm when the number of operation cycle exceeds the set limit, helps preventive maintenance. This can also be used to indicate the requirement for oil sampling for dielectric testing in case of an oil circuit breaker.

The change of state can be detected from the binary input of the auxiliary contact. There is a possibility to set an initial value for the counter which can be used to initialize this functionality after a period of operation or in case of refurbished primary equipment.

**Accumulation of I^y t**

Accumulation of I^y t calculates the accumulated energy ΣI^y t where the factor y is known as the current exponent. The factor y depends on the type of the circuit breaker. For oil circuit breakers the factor y is normally 2. In case of a high-voltage system, the factor y can be 1.4...1.5.

**Remaining life of the breaker**

Every time the breaker operates, the life of the circuit breaker reduces due to wearing. The wearing in the breaker depends on the tripping current, and the remaining life of the breaker is estimated from the circuit breaker trip curve provided by the manufacturer.

**Example for estimating the remaining life of a circuit breaker**
Condition monitoring functions

Figure 203: Trip Curves for a typical 12 kV, 630 A, 16 kA vacuum interrupter

Nr the number of closing-opening operations allowed for the circuit breaker
Ia the current at the time of tripping of the circuit breaker

Calculation of Directional Coefficient

The directional coefficient is calculated according to the formula:

\[
\text{Directional Coef} = \frac{\log \left( \frac{B}{A} \right)}{\log \left( \frac{I_f}{I_r} \right)} = -2.2609
\]

(Equation 42)

I_r Rated operating current = 630 A
I_f Rated fault current = 16 kA
A Op number rated = 30000
B Op number fault = 20

Calculation for estimating the remaining life

The equation shows that there are 30,000 possible operations at the rated operating current of 630 A and 20 operations at the rated fault current 16 kA. Therefore, if the tripping
current is 10 kA, the operation counts from the curve at 10kA is about 60. One operation at 10 kA will result in a reduction in the breaker life by 30,000/60=500 operations. If the remaining life of the circuit breaker is 15,000 operations prior to this tripping, after one operation of 10 kA, the remaining life of the circuit breaker is 15,000-500=14,500 at the rated operating current. Breaker life reduction for one operation at current level I can also be estimated by the following formula,

\[
\text{Remaining life reduction} = \left( \frac{I}{I_r} \right)^{\text{Directional Coef}}
\]

Spring charged indication

For normal operation of the circuit breaker, the circuit breaker spring should be charged within a specified time. Therefore, detecting long spring charging time indicates that it is time for the circuit breaker maintenance. The last value of the spring charging time can be used as a service value.

Gas pressure supervision

The gas pressure supervision monitors the gas pressure inside the arc chamber. When the pressure becomes too low compared to the required value, the circuit breaker operations are locked. A binary input is available based on the pressure levels in the function, and alarms are generated based on these inputs.

6.2.2 Function block

![Function block diagram](image)

*Figure 204: Function block*

6.2.3 Functionality

The fuse failure supervision function SEQRFUF is used to block the voltage measuring functions at a failure in the secondary circuits between the voltage transformer and relay to avoid mis-operations of the voltage protection functions.

SEQRFUF has two algorithms, a negative sequence-based algorithm and a delta current and delta voltage algorithm.

A criterion based on the delta current and the delta voltage measurements can be activated to detect three-phase fuse failures which usually are more associated with the voltage transformer switching during station operations.

6.2.4 Operation principle

The function can be enabled and disabled with the *Operation* setting. The corresponding parameter values are Enable and Disable.

The operation of the fuse failure supervision function can be described by using a module diagram. All the blocks in the diagram are explained in the next sections.
Negative phase-sequence criterion

A fuse failure based on negative phase-sequence criterion is detected if the measured negative phase-sequence voltage exceeds the set $\text{Neg Seq voltage Lev}$ value and the measured negative phase-sequence current is below the set $\text{Neg Seq current Lev}$ value. The detected fuse failure is reported to the decision logic module.

Voltage check

The phase voltage magnitude is checked when deciding whether the fuse failure is a three, two or a single-phase fault.

The module makes a phase-specific comparison between each voltage input and the $\text{Seal in voltage}$ setting. In case the input voltage is lower than the setting, the corresponding phase is reported to the decision logic module.

Current and voltage delta criterion

The delta function can be activated by setting the $\text{Change rate enable}$ parameter to “True”. Once the function is activated, it operates in parallel with the negative phase-sequence based algorithm. The current and voltage are continuously measured in all three phases to calculate:
Condition monitoring functions

- Change of voltage $dU/dt$
- Change of current $dI/dt$

The calculated delta quantities are compared to the respective set values of the \textit{Current change rate} and \textit{Voltage change rate} settings.

The delta current and delta voltage algorithms detect a fuse failure if there is a sufficient negative change in the voltage amplitude without a sufficient change in the current amplitude in each phase separately. This is performed when the circuit breaker is closed. Information about the circuit breaker position is connected to the \texttt{CB\_CLOSED} input.

There are two conditions for activating the current and voltage delta function:

- The magnitude of $\Delta U$ exceeds the corresponding value of the \textit{Min Op voltage delta} setting and the magnitude of $\Delta I$ is below the value of the \textit{Min Op current delta} setting in any phase at the same time due to the closure of the circuit breaker, that is, $\texttt{CB\_CLOSED} = \text{TRUE}$.
- The magnitude of $\Delta U$ exceeds the value of the \textit{Min Op voltage delta} setting and the magnitude of $\Delta I$ is below the \textit{Min Op current delta} setting in any phase at the same time since the magnitude of the phase current in the same phase exceeds the \textit{Current level} setting.

The first condition requires the delta criterion to be fulfilled in any phase at the same time as the circuit breaker is closed. Opening the circuit breaker at one end and energizing the line from the other end onto a fault could lead to an improper operation of SEQRFUF with an open breaker. If this is considered to be an important disadvantage, the \texttt{CB\_CLOSED} input is to be connected to \texttt{FALSE}.

The second condition requires the delta criterion to be fulfilled in one phase together with high current for the same phase. The measured phase current is used to reduce the risk of a false fuse-failure detection. If the current on the protected line is low, a voltage drop in the system (not caused by the fuse failure) is not followed by a current change and a false fuse failure can occur. To prevent this, the minimum phase current criterion is checked.

The fuse-failure detection is active until the voltages return above the \textit{Min Op voltage delta} setting. If a voltage in a phase is below the \textit{Min Op voltage delta} setting, a new fuse failure detection for that phase is not possible until the voltage returns above the setting value.

\textbf{Decision logic}

The fuse-failure detection outputs $\texttt{FUSEF\_U}$ and $\texttt{FUSEF\_3PH}$ are controlled according to the detection criteria or external signals.
### Condition monitoring functions

</tr>
<tr>
<td></td>
<td>The \texttt{FUSEF_U} output signal is also activated if all the phase voltages are above the \textit{Seal in voltage} setting for more than 60 seconds and at the same time the negative sequence voltage is above \textit{Neg Seq voltage Lev} for more than 5 seconds, all the phase currents are below the \textit{Current dead Lin Val} setting and the circuit breaker is closed, that is, \texttt{CB_CLOSED} is \texttt{TRUE}.</td>
</tr>
<tr>
<td>Current and voltage delta function criterion</td>
<td>If the current and voltage delta criterion detects a fuse failure condition, but all the voltages are not below the \textit{Seal in voltage} setting, only the \texttt{FUSEF_U} output is activated.</td>
</tr>
<tr>
<td></td>
<td>If the fuse-failure detection is active for more than five seconds and at the same time all the phase voltage values are below the set value of the \textit{Seal in voltage} setting with \textit{Enable seal in} turned to \textit{Yes}, the function activates the \texttt{FUSE_3PH} output signal.</td>
</tr>
<tr>
<td>External fuse-failure detection</td>
<td>The \texttt{MINCB_OPEN} input signal is supposed to be connected through a relay binary input to the N.C. auxiliary contact of the miniature circuit breaker protecting the VT secondary circuit. The \texttt{MINCB_OPEN} signal sets the \texttt{FUSEF_U} output signal to block all the voltage-related functions when MCB is in the open state.</td>
</tr>
<tr>
<td></td>
<td>The \texttt{DISCON_OPEN} input signal is supposed to be connected through a relay binary input to the N.C. auxiliary contact of the line disconnector. The \texttt{DISCON_OPEN} signal sets the \texttt{FUSEF_U} output signal to block the voltage-related functions when the line disconnector is in the open state.</td>
</tr>
</tbody>
</table>

It is recommended to always set \textit{Enable seal in} to “Yes”. This secures that the blocked protection functions remain blocked until normal voltage conditions are restored if the fuse-failure has been active for 5 seconds, that is, the fuse failure outputs are deactivated when the normal voltage conditions are restored.

The activation of the \texttt{BLOCK} input deactivates both \texttt{FUSEF\_U} and \texttt{FUSE\_3PH} outputs.

#### 6.2.5 Application

Some protection functions operate on the basis of the measured voltage value in the relay point. These functions can fail if there is a fault in the measuring circuits between the voltage transformers and the relay.

A fault in the voltage measuring circuit is referred to as a fuse failure. This term is misleading since a blown fuse is just one of the many possible reasons for a broken circuit.
Since incorrectly measured voltage can result in a mis-operation of some of the protection functions, fast failure detection is one of the means to block voltage-based functions before they operate.

![Figure 206: Fault in a circuit from the voltage transformer to the relay](image)

Figure 206: Fault in a circuit from the voltage transformer to the relay

A fuse failure occurs due to blown fuses, broken wires or intended substation operations. The negative sequence component-based function can be used to detect different types of single-phase or two-phase fuse failures. However, at least one of the three circuits from the voltage transformers must not be broken. The supporting delta-based function can also detect a fuse failure due to three-phase interruptions.

In the negative sequence component-based part of the function, a fuse failure is detected by comparing the calculated value of the negative sequence component voltage to the negative sequence component current. The sequence entities are calculated from the measured current and voltage data for all three phases. The purpose of this function is to block voltage-dependent functions when a fuse failure is detected. Since the voltage dependence differs between these functions, 60 has two outputs for this purpose.

Section 7 Measurement functions

7.1 Basic measurements

7.1.1 Functions

The three-phase current measurement function, IA, IB, IC, is used for monitoring and metering the phase currents of the power system.

The three-phase voltage measurement function, VA, VB, VC, is used for monitoring and metering the phase-to-phase voltages of the power system. The phase-to-ground voltages are also available in VA, VB, VC.

The ground current measurement function, IG, is used for monitoring and metering the ground current of the power system.

The ground voltage measurement function, VG, is used for monitoring and metering the ground voltage of the power system.

The sequence current measurement, I1, I2, I0, is used for monitoring and metering the phase sequence currents.

The sequence voltage measurement, V1, V2, V0, is used for monitoring and metering the phase sequence voltages.

The three-phase power and energy measurement P, SP, E is used for monitoring and metering the active power P, reactive power Q, apparent power S, power factor PF on individual phases as well as three phase total and for calculating the accumulated energy separately on three phase total basis as forward active, reverse active, forward reactive and reverse reactive. P, SP, E calculates these quantities with the fundamental frequency phasors, that is, the DFT values of the measured phase current and phase voltage signals.

The information of the measured quantity is available for the operator both locally in LHMI and remotely to a network control center with communication.

7.1.2 Measurement functionality

The functions can be enabled or disabled with the Operation setting. The corresponding parameter values are Enable and Disable.

Some of the measurement functions operate on two alternative measurement modes: “DFT” and “RMS”. The measurement mode is selected with the X Measurement mode setting. Depending on the measuring function if the measurement mode cannot be selected, the measuring mode is “DFT”.

Demand value calculation

The demand value is calculated separately for each phase. The demand function is implemented by means of a function that calculates the linear average of the signal measured over a settable demand time interval. A new demand value is obtained once in a minute, indicating the analog signal demand over the demand time interval preceding the update time. The actual rolling demand values are stored in the memory until the value is updated at the end of the next time interval. The switching of the demand interval without the loss of data is done by storing the one minute demand values in the memory until the longest demand interval is available. The maximum demand values for each phase are recorded with time stamps. The recorded values are reset with a command.

The demand value calculation is only available in the three-phase current measurement function, IA, IB, IC.

Value reporting

The measurement functions are capable to report new values for network control center (SCADA system) based on the following functions:

- Zero point clamping
- Deadband supervision
- Limit value supervision

In the three-phase voltage measurement function, VA, VB, VC, the supervision functions are based on the phase-to-phase voltages. However, the phase-to-ground voltage values are also reported together with the phase-to-phase voltages.

Zero point clamping

A measured value under zero point clamping limit is forced to zero. This allows the noise in the input signal to be ignored. The active clamping function forces both the actual measurement value and the angle value of the measured signal to zero. In the three-phase or sequence measuring functions, each phase or sequence component has a separate zero point clamping function. The zero value detection operates so that, once the measured value exceeds or falls below the value of zero clamping limit, new values are reported.
### Limit value supervision

The limit value supervision function indicates whether the measured value of $X_{\text{INST}}$ exceeds or falls below the set limits. The measured value has the corresponding range information $X_{\text{RANGE}}$ and has a value in the range of 0 to 4:

- 0: “normal”
- 1: “high”
- 2: “low”
- 3: “high-high”
- 4: “low-low”

The range information changes and the new values are reported.

\(^1\) See Table 276 for limitations.

#### Figure 207: Presentation of operating limits

The range information can also be decoded into boolean output signals on some of the measuring functions and the number of phases required to exceed or undershoot the limit before activating the outputs and can be set with the \textit{Num of phases} setting in the three-phase measurement functions, IA, IB, IC and VA, VB, VC. The limit supervision
boolean alarm and warning outputs can be blocked. The settings involved for limit value supervision are:

### Deadband supervision

The deadband supervision function reports the measured value according to integrated changes over a time period.
The deadband value used in the integral calculation is configured with the \textit{X deadband} setting. The value represents the percentage of the difference between the maximum and minimum limit in the units of 0.001 percent \(*\) seconds.

The reporting delay of the integral algorithms in seconds is calculated with the formula:

\[
\tau(s) = \frac{(\max - \min) \times \text{deadband}}{\Delta Y \times 100}\%.
\]

(Equation 43)

Example for IA, IB, IC:

A deadband = 2500 (2.5\% of the total measuring range of 40)

\[
\text{I INST A} = \text{I DB A} = 0.30
\]

If \text{I INST A} changes to 0.40, the reporting delay is:

\[
\tau(s) = \frac{(40 - 0) \times 2500}{0.40 - 0.30} \times 100\% = 10s
\]
Table 339: Parameters for deadband calculation

<table>
<thead>
<tr>
<th>Function</th>
<th>Settings</th>

<td>V Deadband</td>
<td>4 / 0 (=4xVn)</td>
</tr>
<tr>
<td>Ground current measurement (IG)</td>
<td>A deadband res</td>
<td>40 / 0 (=40xIn)</td>
</tr>
<tr>
<td>Ground voltage measurement (VG)</td>
<td>V deadband res</td>
<td>4 / 0 (=4xVn)</td>
</tr>
<tr>
<td>Phase sequence current measurement (I1, I2, I0)</td>
<td>Ps Seq A deadband, Ng Seq A deadband, Zro A deadband</td>
<td>40 / 0 (=40xIn)</td>
</tr>
<tr>
<td>Phase sequence voltage measurement (V1, V2, V0)</td>
<td>Ps Seq V deadband, Ng Seq V deadband, Zro V deadband</td>
<td>4/0 (=4xVn)</td>
</tr>
<tr>
<td>Three-phase power and energy measurement (P, E)</td>
<td>-</td>
<td></td>
</tr>
</tbody>
</table>

In the three-phase power and energy measurement function, P, E, the deadband supervision is done separately for apparent power S, with the pre-set value of fixed 10 percent of the Sn and the power factor PF, with the pre-set values fixed at 0.10. All the power measurement related values P, Q, S and PF are reported simultaneously when either one of the S or PF values exceeds the pre-set limit.

**Power and energy calculation**

The three-phase power is calculated from the phase-to-ground voltages and phase-to-ground currents. The power measurement function is capable of calculating complex power based on the fundamental frequency component phasors (DFT).

\[ \bar{S} = (\bar{V}_A \cdot \bar{I}_A^* + \bar{V}_B \cdot \bar{I}_B^* + \bar{V}_C \cdot \bar{I}_C^*) \]  \hspace{1cm} (Equation 44)

Once the complex apparent power is calculated, P, Q, S and PF are calculated with the equations:

\[ Q = \text{Im}(\bar{S}) \]  \hspace{1cm} (Equation 45)

\[ Q = \text{Im}(\bar{S}) \]  \hspace{1cm} (Equation 46)

\[ S = |\bar{S}| = \sqrt{P^2 + Q^2} \]  \hspace{1cm} (Equation 47)

\[ \text{Cos} \varphi = \frac{P}{S} \]  \hspace{1cm} (Equation 48)

Depending on the unit multiplier selected with *Power unit Mult*, the calculated power values are presented in units of kVA/kW/kVAr or in units of MVA/MW/MVAr.
The active power $P$ direction can be selected between forward and reverse with Active power Dir and correspondingly the reactive power $Q$ direction can be selected with Reactive power Dir. This affects also the accumulated energy directions.

The accumulated energy is calculated separately as forward active ($EA_{FWD\_ACM}$), reverse active ($EA_{RV\_ACM}$), forward reactive ($ER_{FWD\_ACM}$) and reverse active ($ER_{RV\_ACM}$). Depending on the value of the unit multiplier selected with Energy unit Mult, the calculated power values are presented in units of kWh/kVARh or in units of MWh/MVARh.

When the energy counter reaches its maximum value defined, the counter value is reset and restarted from the zero. Changing the value of the Energy unit Mult setting resets the accumulated energy values to the initial values, that is, $EA_{FWD\_ACM}$ to Forward Wh Initial, $EA_{RV\_ACM}$ to Reverse Wh Initial, $ER_{FWD\_ACM}$ to Forward WArh Initial and $ER_{RV\_ACM}$ to Reverse WArh Initial. It is also possible to reset the accumulated energy to initial values through a parameter or with the RSTACM input.

**Sequence components**

The phase-sequence current components are calculated from the phase currents according to:
The phase-sequence voltage components are calculated from the phase-to-ground voltages when VT connection is selected as “Wye” with the formulae:

\[
\bar{V}_0 = (\bar{V}_A + \bar{V}_B + \bar{V}_C)/3
\]

\[
\bar{V}_1 = (\bar{V}_A + a \cdot \bar{V}_B + a^2 \cdot \bar{V}_C)/3
\]

\[
\bar{V}_2 = (\bar{V}_A + a^2 \cdot \bar{V}_B + a \cdot \bar{V}_C)/3
\]

When VT connection is selected as “Delta”, the positive and negative phase sequence voltage components are calculated from the phase-to-phase voltages according to the formulae:

\[
\bar{V}_1 = (\bar{V}_{AB} - a^2 \cdot \bar{V}_{BC})/3
\]

\[
\bar{V}_2 = (\bar{V}_{AB} - a \cdot \bar{V}_{BC})/3
\]

### 7.1.3 Measurement function applications

The measurement functions are used for power system measurement, supervision and reporting to LHMI, a monitoring tool within PCM600, or to the station level, for example, with IEC 61850. The possibility to continuously monitor the measured values of active power, reactive power, currents, voltages, power factors and so on, is vital for efficient production, transmission, and distribution of electrical energy. It provides a fast and easy overview of the present status of the power system to the system operator. Additionally, it can be used during testing and commissioning of protection and control relays to verify the proper operation and connection of instrument transformers, that is, the current transformers (CTs) and voltage transformers (VTs). The proper operation of the relay analog measurement chain can be verified during normal service by a periodic comparison of the measured value from the relay to other independent meters.

When the zero signal is measured, the noise in the input signal can still produce small measurement values. The zero point clamping function can be used to ignore the noise in the input signal and, hence, prevent the noise to be shown in the user display. The zero clamping is done for the measured analog signals and angle values.

The demand values are used to neglect sudden changes in the measured analog signals when monitoring long time values for the input signal. The demand values are linear average values of the measured signal over a settable demand interval. The demand values are calculated for the measured analog three-phase current signals.
The limit supervision indicates, if the measured signal exceeds or goes below the set limits. Depending on the measured signal type, up to two high limits and up to two low limits can be set for the limit supervision.

The deadband supervision reports a new measurement value if the input signal has gone out of the deadband state. The deadband supervision can be used in value reporting between the measurement point and operation control. When the deadband supervision is properly configured, it helps in keeping the communication load in minimum and yet measurement values are reported frequently enough.

Section 8 Recording functions

8.1 Digital fault recorder DFR (RDRE)

8.1.1 Functionality

The relay is provided with a digital fault recorder featuring up to 12 analog and 64 binary signal channels. The analog channels can be set to record either the waveform or the trend of the currents and voltage measured.

The analog channels can be set to trigger the recording function when the measured value falls below or exceeds the set values. The binary signal channels can be set to start a recording on the rising or the falling edge of the binary signal or both.

By default, the binary channels are set to record external or internal relay signals, for example the start or trip signals of the relay stages, or external blocking or control signals. Binary relay signals such as a protection start or trip signal, or an external relay control signal over a binary input can be set to trigger the recording. The recorded information is stored in a non-volatile memory and can be uploaded for subsequent fault analysis.

8.1.1.1 Recorded analog inputs

The current RER 620 release does not support selection of analog channels for disturbance (DFR) recorder. 10 channels of RDRE/DFR component are pre-mapped to following analog inputs: IL1, IL2, IL3, Io, U1, U2, U3, U2A, U2B, U2C.

All analog inputs of the digital fault recorder that are enabled are included in the recording when triggered appropriately.

8.1.1.2 Triggering alternatives

The recording can be triggered by any or several of the following alternatives:

- Triggering according to the state change of any or several of the binary channels of the digital fault recorder. The user can set the level sensitivity with the Level trigger mode parameter of the corresponding binary channel.
- Triggering on limit violations of the analog channels of the digital fault recorder (high and low limit)
- Manual triggering via the Trig recording parameter (LHMI or communication)
- Periodic triggering.

Regardless of the triggering type, each recording generates events through state changes of the Recording started, Recording made and Recording stored status parameters. The Recording stored parameter indicates that the recording has been stored to the non-volatile memory. In addition, every analog channel and binary channel of the digital fault recorder
has its own Channel triggered parameter. Manual trigger has the Manual triggering parameter and periodic trigger has the Periodic triggering parameter. A state change in any of these parameters also generates an event that gives individual information about the reason of the triggering. COMTRADE files provide unambiguous information about the reason of the triggering, usually only for the binary channels but in some cases also for the analog channels.

**Triggering by binary channels**

Input signals for the binary channels of the digital fault recorder can be formed from any of the digital signals that can be dynamically mapped. A change in the status of a monitored signal triggers the recorder according to the configuration and settings. Triggering on the rising edge of a digital input signal means that the recording sequence starts when the input signal is activated. Correspondingly, triggering on the falling edge means that the recording sequence starts when the active input signal Resets. It is also possible to trigger from both edges. In addition, if preferred, the monitored signal can be non-triggering. The trigger setting can be set individually for each binary channel of the digital fault recorder with the Level trigger mode parameter of the corresponding binary channel.

**Triggering by analog channels**

The trigger level can be set for triggering in a limit violation situation. The user can set the limit values with the High trigger level and Low trigger level parameters of the corresponding analog channel. Both high level and low level violation triggering can be active simultaneously for the same analog channel. If the duration of the limit violation condition exceeds the filter time of approximately 50 ms, the recorder triggers. In case of a low level limit violation, if the measured value falls below approximately 0.05 during the filter time, the situation is considered to be a circuit-breaker operation and therefore, the recorder does not trigger. This is useful especially in undervoltage situations. The filter time of approximately 50 ms is common to all the analog channel triggers of the digital fault recorder. The value used for triggering is the calculated peak-to-peak value. Either high or low analog channel trigger can be disabled by setting the corresponding trigger level parameter to zero.

**Manual triggering**

The recorder can be triggered manually via the LHMI or via communication by setting the Trig recording parameter to TRUE.

**Periodic triggering**

Periodic triggering means that the recorder automatically makes a recording at certain time intervals. The user can adjust the interval with the Periodic trig time parameter. If the value of the parameter is changed, the new setting takes effect when the next periodic triggering occurs. Setting the parameter to zero disables the triggering alternative and the setting becomes valid immediately. If a new non-zero setting needs to be valid immediately, the user should first set the Periodic trig time parameter to zero and then to the new value. The
user can monitor the time remaining to the next triggering with the Time to trigger monitored data which counts downwards.

8.1.2 Length of recordings

The user can define the length of a recording with the Record length parameter. The length is given as the number of fundamental cycles.

According to the memory available and the number of analog channels used, the digital fault recorder automatically calculates the remaining amount of recordings that fit into the available recording memory. The user can see this information with the Rem. amount of rec monitored data. The fixed memory size allocated for the recorder can fit in two recordings that are ten seconds long. The recordings contain data from all analog and binary channels of the digital fault recorder, at the sample rate of 32 samples per fundamental cycle.

The user can view the number of recordings currently in memory with the Number of recordings monitored data. The currently used memory space can be viewed with the Rec. memory used monitored data. It is shown as a percentage value.

The maximum number of recordings is 100.

8.1.2.1 Sampling frequencies

The sampling frequency of the digital fault recorder analog channels depends on the set rated frequency. One fundamental cycle always contains the amount of samples set with the Storage rate parameter. Since the states of the binary channels are sampled once per task execution of the digital fault recorder, the sampling frequency of binary channels is 400 Hz at the rated frequency of 50 Hz and 480 Hz at the rated frequency of 60 Hz.

</tr>
</tbody>
</table>

8.1.2.2 Uploading of recordings

The relay stores COMTRADE files to the C:\COMTRADE\ folder. The files can be uploaded with the PCM tool or any appropriate computer software that can access the C:\COMTRADE\ folder.
One complete disturbance recording consists of two COMTRADE file types: the configuration file and the data file. The file name is the same for both file types. The configuration file has .CFG and the data file .DAT as the file extension.

![Figure 218: Digital fault recorder file naming](image)

The naming convention of 8+3 characters is used in COMTRADE file naming. The file name is composed of the last two octets of the relay's IP number and a running counter, which has a range of 1...9999. A hexadecimal representation is used for the IP number octets. The appropriate file extension is added to the end of the file name.

### 8.1.2.3 Deletion of recordings

There are several ways to delete disturbance recordings. The recordings can be deleted individually or all at once.

Individual disturbance recordings can be deleted with the PCM tool or any appropriate computer software, which can access the relay's `C:\COMTRADE` folder. The disturbance recording is not removed from the relay memory until both of the corresponding COMTRADE files, .CFG and .DAT, are deleted. The user may have to delete both of the files types separately, depending on the software used.

Deleting all disturbance recordings at once is done either with the PCM tool or any appropriate computer software, or from the LHMI via the **Clear/Disturbance records** menu. Deleting all disturbance recordings at once also clears the pre-trigger recording in progress.

### 8.1.2.4 Storage mode

The digital fault recorder can capture data in two modes: waveform and trend mode. The user can set the storage mode individually for each trigger source with the **Storage mode**
parameter of the corresponding analog channel or binary channel, the *Stor. mode manual* parameter for manual trigger and the *Stor. mode periodic* parameter for periodic trigger.

In the waveform mode, the samples are captured according to the *Storage rate* and *Pre-trg length* parameters.

In the trend mode, one RMS value is recorded for each enabled analog channel, once per fundamental cycle. The binary channels of the digital fault recorder are also recorded once per fundamental cycle in the trend mode.

Only post-trigger data is captured in trend mode.

The trend mode enables recording times of $32 \times \text{Record length}$.

### 8.1.2.5 Pre-trigger and post-trigger data

The waveforms of the digital fault recorder analog channels and the states of the digital fault recorder binary channels are constantly recorded into the history memory of the recorder. The user can adjust the percentage of the data duration preceding the triggering, that is, the so-called pre-trigger time, with the *Pre-trg length* parameter. The duration of the data following the triggering, that is, the so-called post-trigger time, is the difference between the recording length and the pre-trigger time. Changing the pre-trigger time resets the history data and the current recording under collection.

### 8.1.2.6 Operation modes

Digital fault recorder has two operation modes: saturation and overwrite mode. The user can change the operation mode of the digital fault recorder with the *Operation mode* parameter.

**Saturation mode**

In saturation mode, the captured recordings cannot be overwritten with new recordings. Capturing the data is stopped when the recording memory is full, that is, when the maximum number of recordings is reached. In this case, the event is sent via the state change (TRUE) of the *Memory full* parameter. When there is memory available again, another event is generated via the state change (FALSE) of the *Memory full* parameter.

**Overwrite mode**

When the operation mode is “Overwrite” and the recording memory is full, the oldest recording is overwritten with the pre-trigger data collected for the next recording. Each time a recording is overwritten, the event is generated via the state change of the *Overwrite of rec.* parameter. The overwrite mode is recommended, if it is more important to have the latest recordings in the memory. The saturation mode is preferred, when the oldest recordings are more important.

New triggerings are blocked in both the saturation and the overwrite mode until the previous recording is completed. On the other hand, a new triggering can be accepted before all pre-trigger samples are collected for the new recording. In such a case, the recording is as much shorter as there were pre-trigger samples lacking.
8.1.2.7 Exclusion mode

Exclusion mode is on, when the value set with the *Exclusion time* parameter is higher than zero. During the exclusion mode, new triggerings are ignored if the triggering reason is the same as in the previous recording. The *Exclusion time* parameter controls how long the exclusion of triggerings of same type is active after a triggering. The exclusion mode only applies to the analog and binary channel triggerings, not to periodic and manual triggerings.

When the value set with the *Exclusion time* parameter is zero, the exclusion mode is disabled and there are no restrictions on the triggering types of the successive recordings.

The exclusion time setting is global for all inputs, but there is an individual counter for each analog and binary channel of the digital fault recorder, counting the remaining exclusion time. The user can monitor the remaining exclusion time with the *Exclusion time rem* parameter of the corresponding analog or binary channel. The *Exclusion time rem* parameter counts downwards.

8.1.3 Configuration

The user can configure the digital fault recorder with the PCM600 tool or any tool supporting the IEC 61850 standard.

The user can enable or disable the digital fault recorder with the *Operation* parameter under the **Configuration/Digital fault recorder/General** menu.

One analog signal type of the relay can be mapped to each of the analog channels of the digital fault recorder. The mapping is done with the *Channel selection* parameter of the corresponding analog channel. The name of the analog channel is user-configurable. The user can modify it by writing the new name to the *Channel id text* parameter of the corresponding analog channel.

Any external or internal digital signal of the relay which can be dynamically mapped can be connected to the binary channels of the digital fault recorder. These signals can be, for example, the start and trip signals from protection function blocks or the external binary inputs of the relay. The connection is made with dynamic mapping to the binary channel of the digital fault recorder using, for example, *SMT* of PCM600. It is also possible to connect several digital signals to one binary channel of the digital fault recorder. In that case, the signals can be combined with logical functions, for example AND and OR. The user can configure the name of the binary channel and modify it by writing the new name to the *Channel id text* parameter of the corresponding binary channel.

Note that the *Channel id text* parameter is used in COMTRADE configuration files as a channel identifier.

The recording always contains all binary channels of the digital fault recorder. If one of the binary channels is disabled, the recorded state of the channel is continuously FALSE and the state changes of the corresponding channel are not recorded. The corresponding channel name for disabled binary channels in the COMTRADE configuration file is *Unused BI*.

To enable or disable a binary channel of the digital fault recorder, the user can set the *Operation* parameter of the corresponding binary channel to the values “on” or “off”.
The states of manual triggering and periodic triggering are not included in the recording, but they create a state change to the Periodic triggering and Manual triggering status parameters, which in turn create events.

The Recording started parameter can be used to control the indication LEDs of the relay. The output of the Recording started parameter is TRUE due to the triggering of the digital fault recorder, until all the data for the corresponding recording is recorded.

The IP number of the relay and the content of the Bay name parameter are both included in the COMTRADE configuration file for identification purposes.

8.1.4 Application

The digital fault recorder is used for post-fault analysis and for verifying the correct operation of protection relays and circuit breakers. It can record both analog and binary signal information. The analog inputs are recorded as instantaneous values and converted to primary peak value units when the relay converts the recordings to the COMTRADE format.

COMTRADE is the general standard format used in storing disturbance recordings.

The binary channels are sampled once per task execution of the digital fault recorder. The task execution interval for the digital fault recorder is the same as for the protection functions. During the COMTRADE conversion, the digital status values are repeated so that the sampling frequencies of the analog and binary channels correspond to each other. This is required by the COMTRADE standard.

The digital fault recorder follows the 1999 version of the COMTRADE standard and uses the binary data file format.

Section 9  Other functions

9.1  Uninterruptible Power Supply UPS

9.1.1  Function block

![Function block diagram](image)

Figure 219: UPS function block

9.1.2  Functionality

The RER620 UPS (Uninterruptible Power Supply) is a subsystem for the RER620 recloser controller. It is implemented in a separate case (see Figure 220) and is powered by the control power which may be AC or DC. The UPS can operate over a wide range of control voltages.

The main UPS function is to enable operation of the RER620 after the loss of control power for a period of time that depends on the amp hour rating of the battery. A 12 amp hour battery will power the total system for about 38 hours with a standard load. The RER620 UPS incorporates a battery management system that includes both battery charging and battery test functions.

The RER620 UPS case includes an auxiliary power output that may be used to power a modem, radio, etc.

There is also a voltage boost function integrated into the RER620 UPS system that provides up to 250Vdc. This power source, in combination with an external capacitor, is used to operate a variety of magnetic actuators.

The UPS incorporates a high current dry contact output that is temperature controlled. This output can be used to switch on and off the low-voltage-cabinet heater.

The RER620 UPS is microprocessor controlled and is capable of external communications through its communications port. The main purpose for this communication is to receive instructions from the RER620 Control and to transmit status, and battery test results to the RER620 Control.
The following sections describe in detail the following functions of the UPS:

- Input power requirements
- Input power measurement
- Loss of input power alarm
- Battery management
- Auxiliary power supply
- Actuator drive power supply (boost supply)
- Heater control switch
- RER620 power
- RS485 commutations
9.1.2.1 Input power requirements

The power input circuit includes surge protection that will react to both differential and common mode noise.

The UPS may be powered by AC or DC. The incoming power supplies a 120 watt DC-to-DC power supply. There are two versions of the UPS. One version covers a 125 Vdc and 120 Vac range, while the other covers a 250 Vdc and 240 Vac range. There is a comparator that monitors the incoming power and will switch off the DC-to-DC if the voltage is not inside a specified tolerance.
9.1.3 Input Power Measurement

The UPS can measure the input voltage if powered by AC. This measurement is accomplished with a capacitor voltage divided (CVD) network.

In pole-mounted applications, the control power is always AC. No UPS internal decisions are made based on the CVD measurement. (The loss-of-control-power alarm is based off the 60 Vdc rail inside the UPS, not the CVD measurement.) The CVD measurement is simply reported back to the RER620, which can report it to central control.

The AC power source in almost all systems has one of its two leads referenced to earth ground. The AC voltage lead that is not referenced to ground is referred to as the Hot lead, or L1. The lead that is referenced to earth ground is referred to as Neutral, or L2. The UPS is expecting a power source that has L2 connected to earth ground, and that lead is to be connected to the UPS L2 connection point.

The UPS AC voltage measurement will draw attention to an incorrectly wired recloser, but there are exceptions. Present AC control power is derived from a residential transformer or a single bushing PT. These power sources have the L2 and earth ground connection at the same potential. It is possible to power an RER recloser from a dual bushing PT where the AC is “floating.” There may even be parts of the world that supplies residents with floating AC. In such a situation, the RER620 will report the voltage off by a significant amount from the actual voltage. The RER620 has an input power calibration function that may be used to correct the voltage measurement in cases where there is no connection between L2 and earth ground, or to increase the accuracy of the measurement.

9.1.3.1 Loss of UPS input power alarm.

The UPS is equipped with a form-C dry contacts that will provide an alarm in the event of power loss. The alarm contacts are energized if input power is present (AC or DC) to the UPS or if the 60 Vdc rail within the UPS is above 57 Vdc. When input power is present, pins 2 and 3 of connector W2 are connected. When there is insufficient power, pins 1 and 2 are connected.

In addition, the Loss of input power alarm is also transmitted to the RER620 via the RS485 communication link.

9.1.3.2 Battery management

Battery management consists of three functions:

- battery test
- battery charging
- battery start

Battery test

This function tests the battery's charge and overall health by briefly connecting a low resistance load parallel to the battery and then measuring the battery voltage. The battery voltage before the load was applied and the voltage during the time the load is applied may be compared to determine battery's health. The load is about 1.5 ohms. The connection time for the load is 0.1 seconds. Ten voltage measurements are taken and averaged together in the last 25 milliseconds of the test period to calculate the battery voltage test measurement. After the battery is tested, a cool down period of around 2 minutes for the UPS's battery load resistors is required. During the cool down period the battery test function is blocked.

If the battery test function is blocked, the output channel "Battery Tested OK" of ZBAT1 function will be FALSE. If the battery function is blocked, the battery test voltage will be zero. The measurements taken during the battery test may be read only once. Then the measurements are zeroed.

Battery charging

The battery charger is designed to charge a 48 Vdc lead-acid battery. The charger has maximum charge wattage of 40 watts. But the charge is firmware controlled in such a way that the full charging wattage is applied only when the battery’s voltage is in the range 30 to 48 Vdc. At the lower end of this range, it is not known whether the battery is very discharged or the battery is defective. If the recloser is operating off batteries, then the system is switched off when the battery voltage reaches about 40 Vdc, so the battery voltage should never be below 40 Vdc. At around 48 to 50 Vdc, the battery charge current is decreased to start the transition to a float or trickle charge mode.

The maximum charge voltage is dependent on temperature. If the batteries are at a high temperature the maximum charge voltage is decreased. At lower temperatures the maximum charge voltage is increased. At room temperature the battery charge voltage is about 55 Vdc.

The boost function has priority over the battery charger. When the UPS is in boost mode the battery charger is off.

Battery start

The UPS has a function that will start the RER620-controlled recloser system if the battery is charged to a voltage of about 44 Vdc. In order to start the UPS using battery power, the power switch S1 must be pressed and held for about five seconds. Once operating using battery power, the RER620 will continue to operate until the battery voltage discharges down to about 40 Vdc, at which time the UPS will disconnect the battery from the system.
If one desires to switch off the system while operating on battery power (before the battery discharges to 40 Vdc), open the battery fuse block.

**9.1.3.3 Auxiliary Power Supply**

The UPS has an isolated 30 watt output Auxiliary Power Supply (APS) for auxiliary equipment such as radios, modems, etc. The APS has two output voltage settings, 12 Vdc and 24 Vdc. The voltage selection is made by communications from the RER620. The supply may be switched on or off by communications as well. In applications where the supply is not needed, switching it off will extend the battery life. Once set, the APS will remember its settings after a UPS system reset. If the supply has never been setup, its default value is 12 Vdc and switched off. The recommended maximum steady load for the APS is 24 watts.

The APS is not fused, but it is protected with protection firmware and hardware that will allow for load power to exceed 24 watts for only limited periods of time. The firmware protection is based on two I2T (Current squared * Time) curves, one fast and one slow. The slow curve will go into pickup at 24 watts and, if just over pickup, will timeout in about 3 minutes. The fast curve will go into pickup at 28 watts and, if just over pickup, will timeout in about 15 seconds. If the APS shuts down due to a timeout on the fast or slow curve, then there is a three minute cool down time. At the expiration of the cool down timer the supply is switched back on and the RER620 is notified. The hardware instantaneous protection circuit will shutdown the APS at about 38 watts and will retry to start the supply about once a second.

**9.1.3.4 Actuator Drive Power Source (Boost Supply)**

The UPS has a programmable power supply that has a range from 60 Vdc to 250 Vdc. The output from this supply provides the power to operate the actuators for the recloser. Usually the voltage selection is made once through communication from the RER620 and left at that setting for the life of the UPS unit. The default voltage is 240 Vdc. The wattage for this power supply may peak as high as 80 watts during fast reclose operations when multiple pole operations are required in quick succession. The power source for this supply is the 60 Vdc rail within the UPS. The voltage from the 60 Vdc rail is increased by means of an inductor, diode, and FET arrangement common in flyback type boost circuits.

This supply has sufficient wattage to harm itself if driving a low impedance load. To help prevent this, there is a 300 ohm resistor used in series with the 60 Vdc rail used to charge the supply’s load. If the load can not be charged to about 40 Vdc through the 300 ohm resistor, then the relay contacts (RA1) that bypass this resistor will not engage. The boost will not operate until RA1 has closed.

The output from this supply will remain charged for many hours after the UPS has been powered down if not discharged with an external load.

**9.1.3.5 Heater control switch**

The heater relay (RA3) is used to control the low-voltage-cabinet heater. The UPS makes use of its integrated temperature sensor to determine when the heater should engage. The UPS can also select to switch off the heater in the event there is no or limited input power.
The heater will not be energized when operating off battery back up power. For example if AC power is limited and a pole operation has just occurred, the heater may be switch off so more available power can go into charging the boost capacitor. This circuit can conduct and switch 8 amps at 250 Vac continuously.

The heater relay (RA3) is connected to connector W2, pins 7 and 8. If the temperature is above 27°C RA3 is always off. If the temperature is below 20°C RA3 is always energized. If the temperature is between 68°F and 81°F (20°C and 27°C), the state of RA3 is determined by a rising temperature or a falling temperature. The temperature sensor is located inside the UPS case, in the corner of the UPS close to the microprocessor.

9.1.3.6 RER620 power

Power to the RER620 is provided by UPS connector W1 pins 7 (+60 Vdc) and 8 (return). This connection can provide about 30 watts. (In normal operation the RER620 will consume about 15 watts.) When the UPS is operating from battery power, the supplied voltage is the battery’s positive voltage. Hence, the voltage range for this power source is 40 Vdc to 60 Vdc.

9.1.3.7 RS485 communications

The communication link between the UPD and the UPS is a half-duplex (2 wires) RS485 serial channel. The UPS RS485 communications link is isolated.

The UPD acts as master, the UPS as slave.

- Transmission speed for the UPD-UPS serial interface (SCI) is fixed at 19200 bps.
- 8 data bits
- No parity
- 1 stop bit

9.1.6 CVD Voltage Clamping

It is possible for some embedded Capacitor Voltage Divider (CVD) sensors to measure, a voltage in excess of +/-4% tolerance, under conditions of extreme humidity or wetting of pole surfaces. The 'CVD clamping' function clamps the measured voltage from the CVD sensors, to within +/- 4% of a reference voltage. The Clamping function is intended to be used with certain types of reclosers, please contact ABB for further clarification.

The necessary reference voltage can be obtained by connecting three external potential transformers (PTs) to the V1abc or V2abc analog inputs of the relay [Refer to Figure 186]. Alternately, in the absence of the three external PTs, the PT used to power up the recloser control cabinet may be used as the reference when connected to the V1abc or V2abc inputs of the relay [Refer to Figure 187]. All applicable limitations are listed at the end of the section.
Connection examples

- With three external PTs

![Connection diagram with three phase PT](image)

**Figure 223:** *Installation with three phase PT*

- Without three external PTs (PT used to power up the recloser is used as reference).

![Connection diagram with single phase PT](image)

**Figure 224:** *Installation with single phase PT*
The CVD Voltage Clamping function is based on the following table, where V1x, x=a,b,c, are the CVD voltage measurements, V2x, x=a,b,c, are the reference PT voltage measurements, and V2n is the nominal voltage defined in the relay structure, Configuration-> Analog inputs->Voltage 2-> Secondary voltage.

**Table 387: Clamping logic**

<table>

<td>V1x = 1.04*V2x</td>
</tr>
<tr>
<td></td>
<td>All other conditions</td>
<td>No clamping</td>
</tr>
</tbody>
</table>

When enabling the CVD Voltage Clamping function, the following assumptions and limitations exist:

1. The Clamping function is applicable only for the Wye-connected PT installation, single or three phase.
2. For single phase PT installation, the CVD clamping is applicable only to a nominal 120Vac low voltage cabinet control power.
3. For single phase PT installation, the voltage based protections and measurement alarms on the reference side should be disabled.
4. The Clamping function affects only the voltage amplitudes.
5. When no reference voltage is available, the Clamping function should be disabled; otherwise, V1 will report the actual CVD values when the poles are open and report zeroes when the poles are closed.
6. If both V1 and V2 are CVDs or both are PTs, the voltages measurements will not be adjusted.
7. It is recommended that voltage based protections are either not used or blocked when the Clamping function is enabled.

9.2 Universal power drive UPD

9.2.1 Function block

The Universal Power Drive (UPD) module is designed specifically for the RER620. It is a two-width module in Slot 2 (X115) of the RER620 case. The UPD module is a single circuit board that provides six half-bridge drivers that are connected to form three independent electrical full-bridge drive channels. Each channel consists of four switches (FET/IGBT) in a bridge arrangement. Two of the switches in each channel are high-side and two are low-side. The purpose of each channel is to allow current flow through an attached load to be in the forward or reverse direction. The intended load for each channel is single coil actuator. Each actuator is mechanically connected to a vacuum bottle switch. The actuator and vacuum bottle make up a single pole. The UPD is normally attached to three poles for control of a three-phase feeder in an electrical distribution system.

Figure 225: UPD function block
Figure 226: Universal Power Drive (UPD) block diagram
The UPD provides six high current drive channels of a proximally 60 amps max, and 250 Vdc maximum. The architecture of the six channels is that of a half bridge driver. When placed in service the six are grouped to form three full bridge drivers, so that each channel will provide its load with either positive or negative current flow. The UPD may drive its load via constant on or PWM method. The constant on mode does not apply to the highside driver, only the lowside.

Control of the UPD is through a parallel bus. The parallel bus is decoded by a CPLD located on the UPD. The CPLD supplies the decoded commands to a TI DSP via an SPI bus. The DSP controls the bridge drives. Data also flows in reverse, from the DSP, to the CPLD, to the parallel bus. The DSP is the master of the SPI bus and the CPLD the slave.

The UPD has an electrically isolated portion to protect the RER620 from electrical disturbances that may be received by the wiring connecting the UPD to the pole top High Voltage Cabinet. This isolated portion of the UPD is powered from two external voltage sources. One is a 250 Vdc source, and the other a 60 Vdc source. There is a switch mode power supply that converts the 60 Vdc to 15 Vdc and 4.2 Vdc.

The UPD is equipped with a two-wire, non-isolated, RS485 communication channel. The primary purpose for this communication channel is to provide a pass through connection between the RER620 CPU board and the UPS.

The UPD is equipped with six, non-isolated binary inputs that are designed for reading switches located in the High Voltage Cabinet.

9.3 Programmable buttons FKEYGGIO

9.3.1 Function block

![Function block diagram](image)

9.3.2 Functionality

The programmable function block FKEYGGIO is a simple interface between the panel and the application. The user input from the buttons available on the front panel is transferred to the assigned functionality and the corresponding LED is turned ON/OFF for indication. The behavior of each function key in the specific application is configured by connection with other application functions. This gives the maximum flexibility.

The LED input and its key output of FKEYGGIO are independent. To make the led on a pushbutton follow the state of the pushbutton, external glue logic is needed. The status of FKEYGGIO inputs and outputs are NOT saved to non-volatile memory.

9.4  Move function block MVGAPC

9.4.1  Function block

Figure 229:  Function block

9.4.2  Functionality

The move function block MVGAPC is used for user logic bits. Each input state is directly copied to the output state. This allows the creating of events from advanced logic combinations.

9.6 Generic control points SPCGGIO

9.6.1 Function block

![Function block diagram]

9.6.2 Functionality

The generic control points function block SPCGGIO can be used in combination with other function blocks such as FKEYGGIO. This block offers the capability to activate its output through a local or remote control. The local control is issued through the buttons in the front panel and the remote control is issued through communications. This block has two modes of operation. In pulsed mode, regardless of local or remote, the block generates an output pulse of preset duration. In toggle mode, a local pushbutton simply toggles the output signal for every input pulse received, whereas a remote command only does SET/RESET.

<table>
<thead>
<tr>
<th>SPCSO1.output</th>
<th>Remote Command</th>
<th>SPCSO1.output</th>
</tr>
</thead>
<tbody>
<tr>
<td>TRUE</td>
<td>⇔ SET</td>
<td>⇔ TRUE</td>

<td>⇔ FALSE</td>
</tr>
<tr>
<td>FALSE</td>
<td>⇔ SET</td>
<td>⇔ TRUE</td>
</tr>
<tr>
<td>FALSE</td>
<td>⇔ RESET</td>
<td>⇔ FALSE</td>
</tr>
</tbody>
</table>

The status of SPCGGIO outputs ARE saved to non-volatile memory, so the relay can memorize these outputs even when power is cycled.

The input and output of SPCGGIO are mapped to the same IEC 61850 data path. Any ACT block that is connected to the input of a SPCGGIO must have a smaller execution order than SPCGGIO.

9.7 Set-reset flip flops SRGAPC

9.7.1 Function block

![Function block diagram]

Figure 233: Function block

9.7.2 Functionality

The SRGAPC function block is a simple SR flip-flop with a memory that can be set or that can reset an output from the S# or R# inputs, respectively. SRGAPC contains eight independent set-reset flip-flop latches where the SET input has the higher priority over the RESET input. The status of each Q# output is retained in the nonvolatile memory. The individual reset for each Q# output is available on the LHMI or through tool via communication.

9.8 Time-delay-off timers TOFGAPC

9.8.1 Function block

9.8.2 Functionality

The time-delay-off function block TOFGAPC can be used, for example, for a drop-off-delayed output related to the input signal. TOFGAPC contains eight independent timers. There is a settable delay in the timer. Once the input is activated, the output is set immediately. When the input is cleared, the output stays on until the time set with the Off delay time setting has elapsed.

Section 10    General function block features

10.1    Definite time characteristics

10.1.1    Definite time operation

The DT mode is enabled when the Operating curve type setting is selected either as “ANSI Def. Time” or “IEC Def. Time”. In the DT mode, the TRIP output of the function is activated when the time calculation exceeds the set Trip delay time.

The user can determine the reset in the DT mode with the Reset delay time setting, which provides the delayed reset property when needed.

The Type of reset curve setting has no effect on the reset method when the DT mode is selected, but the reset is determined solely with the Reset delay time setting.

Figure 238: Operation of the counter in drop-off

In case 1, the reset is delayed with the Reset delay time setting and in case 2, the counter is reset immediately, because the Reset delay time setting is set to zero.
When the drop-off period is longer than the set *Reset delay time*, as described in Figure 221, the input signal for the definite timer (here: timer input) is active, provided that the current is above the set *Pickup value*. The input signal is inactive when the current is below the set *Pickup value* and the set hysteresis region. The timer input rises when a fault current is detected. The definite timer activates the *PICKUP* output and the trip timer starts elapsing. The reset (drop-off) timer starts when the timer input falls, that is, the fault disappears. When the reset (drop-off) timer elapses, the trip timer is reset. Since this happens before another pickup occurs, the *TRIP* output is not activated.
When the drop-off period is shorter than the set Reset delay time, as described in Figure 222, the input signal for the definite timer (here: timer input) is active, provided that the current is above the set Pickup value. The input signal is inactive when the current is below the set Pickup value and the set hysteresis region. The timer input rises when a fault current is detected. The definite timer activates the PICKUP output and the trip timer starts elapsing. The reset (drop-off) timer starts when the timer input falls, that is, the fault disappears. Another fault situation occurs before the reset (drop-off) timer has elapsed. This causes the activation of the TRIP output, since the trip timer already has elapsed.
Figure 241: Operating effect of the BLOCK input when the selected blocking mode is "Freeze timer"

If the BLOCK input is activated when the trip timer is running, as described in Figure 223, the timer is frozen during the time BLOCK remains active. If the timer input is not active longer than specified by the Reset delay time setting, the trip timer is reset in the same way as described in Figure 221, regardless of the BLOCK input.

The selected blocking mode is “Freeze timer”.
10.2 Current based inverse definite minimum time characteristics

10.2.1 IDMT curves for overcurrent protection

In inverse-time modes, the trip time depends on the momentary value of the current: the higher the current, the faster the trip time. The trip time calculation or integration starts immediately when the current exceeds the set **Pickup value** and the **PICKUP** output is activated.

The **TRIP** output of the component is activated when the cumulative sum of the integrator calculating the overcurrent situation exceeds the value set by the inverse-time mode. The set value depends on the selected curve type and the setting values used. The user determines the curve scaling with the **Time multiplier** setting.

The **Minimum trip time** setting defines the minimum trip time for the IDMT mode, that is, it is possible to limit the IDMT based trip time for not becoming too short. For example:
Figure 242: Trip time curves based on IDMT characteristic with the value of the Minimum trip time setting = 0.5 second
10.2.1.1 Standard inverse-time characteristics

For inverse-time operation, both IEC and ANSI/IEEE standardized inverse-time characteristics are supported.

The trip times for the ANSI and IEC IDMT curves are defined with the coefficients A, B and C.

The values of the coefficients can be calculated according to the formula:
Section 10
General function block features

\[ t[s] = \left( \frac{A}{\left( \frac{I}{I_\text{> set}} \right)^C} + B \right) \cdot k \]

The maximum guaranteed measured current is 50 x In for the current protection. When the set *Pickup value* exceeds 1.00 x In, the turn point where the theoretical IDMT characteristics are leveling out to the definite time can be calculated with the formula:

\[ \text{Turn point} = \frac{50 \times \text{In}}{\text{Pickup value}} \]  
\( (\text{Equation 58}) \)

10.2.1.3 User-programmable inverse-time characteristics

The user can define curves by entering parameters into the following standard formula:

\[
t[s] = \left( \frac{A}{\left( \frac{I}{I^{\ge}} \right)^C} + B \right) \cdot k
\]

(Equation 59)

- \(t[s]\): Trip time (in seconds)
- \(A\): set Curve parameter \(A\)
- \(B\): set Curve parameter \(B\)
- \(C\): set Curve parameter \(C\)
- \(E\): set Curve parameter \(E\)
- \(I\): Measured current
- \(I^{\ge}\): set Pickup value
- \(k\): set Time multiplier

10.2.1.4 RI and RD-type inverse-time characteristics

The RI-type simulates the behavior of electromechanical relays. The RD-type is a ground-fault specific characteristic.

The RI-type is calculated using the formula

\[
t[s] = \frac{k}{0.339 - 0.236 \times \frac{I^{\ge}}{I}}
\]

(Equation 60)

The RD-type is calculated using the formula

\[
t[s] = 5.8 - 1.35 \times \ln \left( \frac{I}{k \times I^{\ge}} \right)
\]

(Equation 61)

- \(t[s]\): Trip time (in seconds)
- \(k\): set Time multiplier
- \(I\): Measured current
- \(I^{\ge}\): set Pickup value
Figure 296: RI-type inverse-time characteristics
Figure 297: RD-type inverse-time characteristics
10.2.2 Reset in inverse-time modes

The user can select the reset characteristics by using the Type of reset curve setting as follows:

**Table 423: Values for reset mode**

<table>
<thead>
<tr>
<th>Setting name</th>
<th>Possible values</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type of reset curve</td>
<td>1=Immediate, 2=Def time reset, 3=Inverse reset</td>
</tr>
</tbody>
</table>

**Immediate reset**

If the Type of reset curve setting in a drop-off case is selected as “Immediate”, the inverse timer resets immediately.

**Definite time reset**

The definite type of reset in the inverse-time mode can be achieved by setting the Type of reset curve parameter to “Def time reset”. As a result, the trip inverse-time counter is frozen for the time determined with the Reset delay time setting after the current drops below the set Pickup value, including hysteresis. The integral sum of the inverse-time counter is reset, if another pickup does not occur during the reset delay.

- If the Type of reset curve setting is selected as “Def time reset”, the current level has no influence on the reset characteristic.

**Inverse reset**

Inverse reset curves are available only for ANSI and user-programmable curves. If you use other curve types, immediate reset occurs.

**Standard delayed inverse reset**

The reset characteristic required in ANSI (IEEE) inverse-time modes is provided by setting the Type of reset curve parameter to “Inverse reset”. In this mode, the time delay for reset is given with the following formula using the coefficient D, which has its values defined in the table below.

\[
t[s] = \left(\frac{D}{\left(\frac{I}{I_{>}}\right)^{2} - 1}\right) k
\]

(Equation 62)

Figure 303: ANSI long-time very inverse reset time characteristics
Figure 304: ANSI long-time inverse reset time characteristics
User-programmable delayed inverse reset

The user can define the delayed inverse reset time characteristics with the following formula using the set Curve parameter D.

\[ t[s] = \left( \frac{D}{\left(\frac{I}{I_>}\right)^2 - 1} \right) \cdot k \]

(Equation 63)

- \( t[s] \): Reset time (in seconds)
- \( k \): set Time multiplier
- \( D \): set Curve parameter D
- \( I \): Measured current
- \( I_> \): set Pickup value

10.2.3 Inverse-timer freezing

When the BLOCK input is active, the internal value of the time counter is frozen at the value of the moment just before the freezing. Freezing of the counter value is chosen when the user does not wish the counter value to count upwards or to be reset. This may be the case, for example, when the inverse-time function of a relay needs to be blocked to enable the definite-time operation of another relay for selectivity reasons, especially if different relaying techniques (old and modern relays) are applied.

The selected blocking mode is “Freeze timer”.

The activation of the BLOCK input also lengthens the minimum delay value of the timer.

Activating the BLOCK input alone does not affect the operation of the PICKUP output. It still becomes active when the current exceeds the set Pickup value, and inactive when the current falls below the set Pickup value and the set Reset delay time has expired.
10.3 Voltage based inverse definite minimum time characteristics

10.3.1 IDMT curves for overvoltage protection

In inverse-time modes, the trip time depends on the momentary value of the voltage, the higher the voltage, the faster the trip time. The trip time calculation or integration starts immediately when the voltage exceeds the set value of the Pickup value setting and the PICKUP output is activated.

The TRIP output of the component is activated when the cumulative sum of the integrator calculating the overvoltage situation exceeds the value set by the inverse time mode. The set value depends on the selected curve type and the setting values used. The user determines the curve scaling with the Time multiplier setting.

The Minimum trip time setting defines the minimum trip time for the IDMT mode, that is, it is possible to limit the IDMT based trip time for not becoming too short. For example:
Figure 305: Trip time curve based on IDMT characteristic with Minimum trip time set to 0.5 second
Figure 306: Trip time curve based on IDMT characteristic with Minimum trip time set to 1 second
10.3.1.1 Standard inverse-time characteristics for overvoltage protection

The trip times for the standard overvoltage IDMT curves are defined with the coefficients A, B, C, D and E.

The inverse trip time can be calculated with the formula:

\[
 t[s] = \frac{k \cdot A}{\left( B \times \frac{V - V_\text{>}}{V_\text{>}} - C \right)^E + D}
\]

(Equation 64)

- \( t \) [s] trip time in seconds
- \( V \) measured voltage
- \( V_\text{>} \) the set value of Pickup value
- \( k \) the set value of Time multiplier

Section 10
General function block features

Figure 307: Inverse curve A characteristic of overvoltage protection
Figure 308: Inverse curve B characteristic of overvoltage protection
Figure 309: Inverse curve C characteristic of overvoltage protection

10.3.1.2 User programmable inverse-time characteristics for overvoltage protection
The user can define the curves by entering the parameters using the standard formula:

\[ t[s] = \frac{k \cdot A}{B \times \frac{V - V_\text{>}}{V_\text{>}} - C} + D \]

(Equation 65)

- \( t[s] \) trip time in seconds
- \( A \) the set value of Curve parameter A
- \( B \) the set value of Curve parameter B
- \( C \) the set value of Curve parameter C
- \( D \) the set value of Curve parameter D
- \( E \) the set value of Curve parameter E
- \( V \) measured voltage
- \( V_\text{>} \) the set value of Pickup value
- \( k \) the set value of Time multiplier

### 10.3.1.3 IDMT curve saturation of overvoltage protection

For the overvoltage IDMT mode of operation, the integration of the trip time does not start until the voltage exceeds the value of Pickup value. To cope with discontinuity characteristics of the curve, a specific parameter for saturating the equation to a fixed value is created. The Curve Sat Relative setting is the parameter and it is given in percents compared to Pickup value. For example, due to the curve equation B and C, the characteristics equation output is saturated in such a way that when the input voltages are in the range of Pickup value to Curve Sat Relative in percent over Pickup value, the equation uses \( \text{Pickup value} \times (1.0 + \text{Curve Sat Relative} / 100) \) for the measured voltage. Although, the curve A has no discontinuities when the ratio \( V/V_\text{>} \) exceeds the unity, Curve Sat Relative is also set for it. The Curve Sat Relative setting for curves A, B and C is 2.0 percent. However, it should be noted that the user must carefully calculate the curve characteristics concerning the discontinuities in the curve when the programmable curve equation is used. Thus, the Curve Sat Relative parameter gives another degree of freedom to move the inverse curve on the voltage ratio axis and it effectively sets the maximum trip time for the IDMT curve because for the voltage ratio values affecting by this setting, the operation time is fixed, that is, the definite time, depending on the parameters but no longer the voltage.

### 10.3.2 IDMT curves for undervoltage protection

In the inverse-time modes, the trip time depends on the momentary value of the voltage, the lower the voltage, the faster the trip time. The trip time calculation or integration starts immediately when the voltage goes below the set value of the Pickup value setting and the PICKUP output is activated.

The TRIP output of the component is activated when the cumulative sum of the integrator calculating the undervoltage situation exceeds the value set by the inverse-time mode. The set value depends on the selected curve type and the setting values used. The user determines the curve scaling with the Time multiplier setting.
The *Minimum trip time* setting defines the minimum trip time possible for the IDMT mode. For setting a value for this parameter, the user should carefully study the particular IDMT curve.

**10.3.2.1 Standard inverse-time characteristics for undervoltage protection**

The trip times for the standard undervoltage IDMT curves are defined with the coefficients A, B, C, D and E.

The inverse trip time can be calculated with the formula:

\[
\begin{align*}
t [s] &= \frac{k \cdot A}{\left( B \times \left( \frac{V < V^<}{V^<} \right) \right) + D} \\
\end{align*}
\]

(Equation 66)

\( t [s] \) trip time in seconds  
\( V \) measured voltage  
\( V^< \) the set value of the *Pickup value setting*  
\( k \) the set value of the *Time multiplier setting*

Figure 310: Inverse curve A characteristic of undervoltage protection
Figure 311: Inverse curve B characteristic of undervoltage protection

10.3.2.2 User-programmable inverse-time characteristics for undervoltage
The user can define curves by entering parameters into the standard formula:

\[
\begin{align*}
t[s] &= \frac{k \cdot A}{B \cdot V < -V < C}^E + D \\
\end{align*}
\]

(Equation 67)

- \(t[s]\): trip time in seconds
- \(A\): the set value of Curve parameter A
- \(B\): the set value of Curve parameter B
- \(C\): the set value of Curve parameter C
- \(D\): the set value of Curve parameter D
- \(E\): the set value of Curve parameter E
- \(V\): measured voltage
- \(V<\): the set value of Pickup value
- \(k\): the set value of Time multiplier

### 10.3.2.3 IDMT curve saturation of undervoltage protection

For the undervoltage IDMT mode of operation, the integration of the trip time does not start until the voltage falls below the value of Pickup value. To cope with discontinuity characteristics of the curve, a specific parameter for saturating the equation to a fixed value is created. The Curve Sat Relative setting is the parameter and it is given in percents compared with Pickup value. For example, due to the curve equation B, the characteristics equation output is saturated in such a way that when input voltages are in the range from Pickup value to Curve Sat Relative in percents under Pickup value, the equation uses Pickup value * (1.0 - Curve Sat Relative / 100) for the measured voltage. Although, the curve A has no discontinuities when the ratio \(V/V>\) exceeds the unity, Curve Sat Relative is set for it as well. The Curve Sat Relative setting for curves A, B and C is 2.0 percent. However, it should be noted that the user must carefully calculate the curve characteristics concerning also discontinuities in the curve when the programmable curve equation is used. Thus, the Curve Sat Relative parameter gives another degree of freedom to move the inverse curve on the voltage ratio axis and it effectively sets the maximum trip time for the IDMT curve because for the voltage ratio values affecting by this setting, the operation time is fixed, that is, the definite time, depending on the parameters but no longer the voltage.

### 10.4 Measurement modes

In many current or voltage dependent function blocks, there are four alternative measuring principles:

- RMS
- DFT which is a numerically calculated fundamental component of the signal
- Peak-to-peak
- Peak-to-peak with peak backup
Consequently, the measurement mode can be selected according to the application. In extreme cases, for example with high overcurrent or harmonic content, the measurement modes function in a slightly different way. The operation accuracy is defined with the frequency range of $f/f_n=0.95...1.05$. In peak-to-peak and RMS measurement modes, the harmonics of the phase currents are not suppressed, whereas in the fundamental frequency measurement the suppression of harmonics is at least -50 dB at the frequency range of $f= n \times f_n$, where $n = 2, 3, 4, 5,...$

**RMS**

The RMS measurement principle is selected with the *Measurement mode* setting using the value “RMS”. RMS consists of both AC and DC components. The AC component is the effective mean value of the positive and negative peak values. RMS is used in applications where the effect of the DC component must be taken into account.

RMS is calculated according to the formula:

$$I_{RMS} = \sqrt{\frac{1}{n} \sum_{i=1}^{n} I_i^2}$$  \hspace{1cm} (Equation 68)

$n$ the number of samples in a calculation cycle

$I_i$ the current sample value

**DFT**

The DFT measurement principle is selected with the *Measurement mode* setting using the value “DFT”. In the DFT mode, the fundamental frequency component of the measured signal is numerically calculated from the samples. In some applications, for example, it can be difficult to accomplish sufficiently sensitive settings and accurate operation of the low stage, which may be due to a considerable amount of harmonics on the primary side currents. In such a case, the operation can be based solely on the fundamental frequency component of the current. In addition, the DFT mode has slightly higher CT requirements than the peak-to-peak mode, if used with high and instantaneous stages.

**Peak-to-peak**

The peak-to-peak measurement principle is selected with the *Measurement mode* setting using the value “Peak-to-Peak”. It is the fastest measurement mode, in which the measurement quantity is made by calculating the average from the positive and negative peak values. The DC component is not included. The retardation time is short. The damping of the harmonics is quite low and practically determined by the characteristics of the anti-aliasing filter of the relay inputs. Consequently, this mode is usually in conjunction with high and instantaneous stages, where the suppression of harmonics is not so important. In addition, the peak-to-peak mode allows considerable CT saturation without impairing the performance of the operation.
Peak-to-peak with peak backup

The peak-to-peak with peak backup measurement principle is selected with the Measurement mode setting using the value “P-to-P+backup”. It is similar to the peak-to-peak mode, with the exception that it has been enhanced with the peak backup. In the peak-to-peak with peak backup mode, the function starts with two conditions: the peak-to-peak value is above the set pickup current or the peak value is above two times the set Pickup value. The peak backup is enabled only when the function is used in the DT mode in high and instantaneous stages for faster operation.
Section 10
General function block features
Section 11 Requirements for measurement transformers

11.1 Current transformers

11.1.1 Current transformer requirements for non-directional overcurrent protection

For reliable and correct operation of the overcurrent protection, the CT has to be chosen carefully. The distortion of the secondary current of a saturated CT may endanger the operation, selectivity, and co-ordination of protection. However, when the CT is correctly selected, a fast and reliable short circuit protection can be enabled.

The selection of a CT depends not only on the CT specifications but also on the network fault current magnitude, desired protection objectives, and the actual CT burden. The protection settings of the relay should be defined in accordance with the CT performance as well as other factors.

Appropriate 'C' class CT should be used based on the total resistances of the CT secondary circuit. If other accuracy class CTs are used then refer the following discussions.

11.1.1.1 Current transformer accuracy class and accuracy limit factor

The rated accuracy limit factor \( F_n \) is the ratio of the rated accuracy limit primary current to the rated primary current. For example, a protective current transformer of type 5P10 has the accuracy class 5P and the accuracy limit factor 10. For protective current transformers, the accuracy class is designed by the highest permissible percentage composite error at the rated accuracy limit primary current prescribed for the accuracy class concerned, followed by the letter “P” (meaning protection).

<table>
<thead>
<tr>
<th>Accuracy class</th>
<th>Current error at rated primary current (%)</th>
<th>Phase displacement at rated primary current minutes</th>
<th>Composite error at rated accuracy limit primary current (%)</th>
</tr>
</thead>
<tbody>
<tr>
<td>5P</td>
<td>±1</td>
<td>±60</td>
<td>±1.8 5</td>
</tr>
<tr>
<td>10P</td>
<td>±3</td>
<td>-</td>
<td>- 10</td>
</tr>
</tbody>
</table>

The accuracy classes 5P and 10P are both suitable for non-directional overcurrent protection. The 5P class provides a better accuracy. This should be noted also if there are accuracy requirements for the metering functions (current metering, power metering, and so on) of the relay.

The CT accuracy primary limit current describes the highest fault current magnitude at which the CT fulfils the specified accuracy. Beyond this level, the secondary current of the CT is distorted and it might have severe effects on the performance of the protection relay.
In practise, the actual accuracy limit factor \( F_a \) differs from the rated accuracy limit factor \( F_n \) and is proportional to the ratio of the rated CT burden and the actual CT burden.

The actual accuracy limit factor is calculated using the formula:

\[
F_a = F_n \times \frac{S_{\text{in}} + S}{S_{\text{in}}}
\]

- \( F_n \) is the accuracy limit factor with the nominal external burden \( S_n \)
- \( S_{\text{in}} \) is the internal secondary burden of the CT
- \( S \) is the actual external burden

### 11.1.1.2 Non-directional overcurrent protection

#### The current transformer selection

Non-directional overcurrent protection does not set high requirements on the accuracy class or on the actual accuracy limit factor \( F_a \) of the CTs. It is, however, recommended to select a CT with \( F_a \) of at least 20.

The nominal primary current \( I_{1n} \) should be chosen in such a way that the thermal and dynamic strength of the current measuring input of the relay is not exceeded. This is always fulfilled when

\[
I_{1n} > \frac{I_{k\text{max}}}{100},
\]

\( I_{k\text{max}} \) is the highest fault current.

The saturation of the CT protects the measuring circuit and the current input of the relay. For that reason, in practice, even a few times smaller nominal primary current can be used than given by the formula.

#### Recommended pickup current settings

If \( I_{k\text{min}} \) is the lowest primary current at which the highest set overcurrent stage is to trip, the pickup current should be set using the formula:

\[
\text{Current pickup value} < 0.7 \times \left( \frac{I_{k\text{min}}}{I_{1n}} \right)
\]

\( I_{1n} \) is the nominal primary current of the CT.

The factor 0.7 takes into account the protection relay inaccuracy, current transformer errors, and imperfections of the short circuit calculations.

The adequate performance of the CT should be checked when the setting of the high set stage overcurrent protection is defined. The trip time delay caused by the CT saturation is typically small enough when the overcurrent setting is noticeably lower than \( F_a \).

When defining the setting values for the low set stages, the saturation of the CT does not need to be taken into account and the pickup current setting is simply according to the formula.
Delay in operation caused by saturation of current transformers

The saturation of CT may cause a delayed relay operation. To ensure the time selectivity, the delay must be taken into account when setting the trip times of successive relays.

With definite time mode of operation, the saturation of CT may cause a delay that is as long as the time constant of the DC component of the fault current, when the current is only slightly higher than the pickup current. This depends on the accuracy limit factor of the CT, on the remanence flux of the core of the CT, and on the trip time setting.

With inverse time mode of operation, the delay should always be considered as being as long as the time constant of the DC component.

With inverse time mode of operation and when the high-set stages are not used, the AC component of the fault current should not saturate the CT less than 20 times the pickup current. Otherwise, the inverse operation time can be further prolonged. Therefore, the accuracy limit factor $F_a$ should be chosen using the formula:

$$F_a > 20 \times \text{Current pickup value} / I_{1n}$$

The Current pickup value is the primary pickup current setting of the relay.

11.1.1.3 Example for non-directional overcurrent protection

The following figure describes a typical medium voltage feeder. The protection is implemented as three-stage definite time non-directional overcurrent protection.

![Figure 312: Example of three-stage overcurrent protection](image)

The maximum three-phase fault current is 41.7 kA and the minimum three-phase short circuit current is 22.8 kA. The actual accuracy limit factor of the CT is calculated to be 59.

The pickup current setting for low-set stage (51P) is selected to be about twice the nominal current of the cable. The trip time is selected so that it is selective with the next relay (not visible in the figure above). The settings for the high-set stage and instantaneous stage are defined also so that grading is ensured with the downstream protection. In addition, the pickup current settings have to be defined so that the relay operates with the minimum fault
current and it does not trip with the maximum load current. The settings for all three stages are as in the figure above.

For the application point of view, the suitable setting for instantaneous stage (50P-3) in this example is 3 500 A (5.83 x I_{2n}). For the CT characteristics point of view, the criteria given by the current transformer selection formula is fulfilled and also the relay setting is considerably below the F_a. In this application, the CT rated burden could have been selected much lower than 10 VA for economical reasons.
Section 12    Relay physical connections

All external circuits are connected to the terminals on the rear panel of the relay.

- Connect each signal connector (X100 and X110) terminal with one 14 or 16 Gauge wire. Use 12 or 14 Gauge wire for CB trip circuit.
- Connect each ring-lug terminal for signal connector X120 with one of maximum 14 or 16 Gauge wire.
- Connect each ring-lug terminal for CTs/VTs with one 12 Gauge wire.

12.1 Protective ground connections

Figure 313: The protective ground screw is located between connectors X100 and X105

The ground lead must be at least 4.0 mm² and as short as possible.

12.2 Communication connections

The front communication connection is an RJ-45 type connector used mainly for configuration and setting.

Depending on order code, several rear port communication connections are available.
12.2.1 Ethernet RJ-45 front connection

The relay is provided with an RJ-45 connector on the LHMI. The connector is mainly for configuration and setting purposes. The interface on the PC side has to be configured in a way that it obtains the IP address automatically. There is a DHCP server inside relay for the front interface only.

The events and setting values and all input data such as memorized values and disturbance records can be read via the front communication port.

Only one of the possible clients can be used for parametrization at a time.

- PCM600
- LHMI
- WHMI

The default IP address of the relay through this port is 192.168.0.254.

The front port supports TCP/IP protocol. A standard Ethernet CAT 5 crossover cable is used with the front port.

The speed of the front connector interface is limited to 10 Mbps.

12.2.2 Ethernet rear connections

The Ethernet communication module is provided with either galvanic RJ-45 connection or optical multimode LC type connection depending on the product variant and selected communication interface option. A shielded twisted-pair cable CAT 5e is used with RJ-45, and an optical cable (≤2 km) with LC type connections.

The relay's default IP address through this port is 192.168.2.10 with the TCP/IP protocol. The data transfer rate is 100 Mbps.

The rear and front ethernet ports must be in the different networks.

12.2.3 EIA-232 serial rear connection

The EIA-232 connection follows the TIA/EIA-232 standard and is intended to be used with a point-to-point connection. The connection supports hardware flow control (RTS, CTS, DTR, DSR), full-duplex and half-duplex communication.
12.2.4 **EIA-485 serial rear connection**

The EIA-485 communication module follows the TIA/EIA-485 standard and is intended to be used in a daisy-chain bus wiring scheme with 2-wire half-duplex or 4-wire full-duplex, multi-point communication.

*The maximum number of devices (nodes) connected to the bus where the relay is used is 32, and the maximum length of the bus is 1200 meters.*

12.2.5 **Optical ST serial rear connection**

Serial communication can be used optionally through an optical connection either in loop or star topology. The connection idle state is light on or light off.

12.2.6 **Communication interfaces and protocols**

The communication protocols supported depend on the optional rear communication module.
### 12.2.7 Rear communication modules

### 12.2.7.1 COMBO22/23A jumper locations and connections

The optional communication module supports EIA-232/EIA-485 serial communication (X6 connector), EIA-485 serial communication (X5 connector) and optical ST serial communication (X12 connector).

Two independent communication ports are supported. The two 2-wire-ports are called COM1 and COM2. Alternatively, if only one 4-wire-port is configured, the port is called COM2. The fibre-optic ST connection uses the COM2 port.

1. Depending on the jumper configuration
COM1 port connection type can be either EIA-232 or EIA-485. Type is selected by setting jumpers X19, X20, X21, X26.

The jumpers are set to EIA-232 by default.
To ensure fail-safe operation, the bus is to be biased at one end using the pull-up and pull-down resistors on the communication module. In the 4-wire connection, the pull-up and pull-down resistors are selected by setting jumpers X5, X6, X8, X9 to enabled position. The bus termination is selected by setting jumpers X7, X11 to enabled position.

The jumpers have been set to no termination and no biasing as default.

Section 16  Glossary

615/RER620  Series of numerical relays for basic, inexpensive and simple protection and supervision applications of utility substations, and industrial switchgear and equipment

100BASE-FX  A physical media defined in the IEEE 802.3 Ethernet standard for local area networks (LANs) that uses fibre-optic cabling

100BASE-TX  A physical media defined in the IEEE 802.3 Ethernet standard for local area networks (LANs) that uses twisted-pair cabling category 5 or higher with RJ-45 connectors

ANSI  American National Standards Institute

AR  Auto-Recloser

CAT 5  A twisted pair cable type designed for high signal integrity

CAT 5e  An enhanced version of CAT 5 that adds specifications for far end crosstalk

CB  Circuit breaker

CBB  Cycle building block

CPU  Central processing unit

CT  Current transformer

CTS  Clear to send

DFR  Digital fault recorder

DFT  Discrete Fourier Transform

DHCP  Dynamic Host Configuration Protocol

DNP3  A distributed network protocol originally developed by Westronic. The DNP3 Users Group has the ownership of the protocol and assumes responsibility for its evolution.

DSR  Data set ready

DT  Definite time

DTR  Data terminal ready

EEPROM  Electrically erasable programmable read-only memory

EIA-232  Serial communication standard according to Electronics Industries Association

EIA-485  Serial communication standard according to Electronics Industries Association

EMC  Electromagnetic compatibility

FPGA  Field programmable gate array

GOOSE  Generic Object Oriented Substation Event
