Overview of this manual

About this manual

This is a reference manual containing a detailed explanation of the programming language as well as all instructions, functions, and data types. This manual is particularly useful when programming offline. Inexperienced users should start with Operating manual - OmniCore.

This manual describes RobotWare 7.

Usage

This manual should be read during programming.

Who should read this manual?

This manual is intended for someone with some previous experience in programming, for example, a robot programmer.

Organization of chapters

The manual is organized in the following chapters:

<table>
<thead>
<tr>
<th>Chapter</th>
<th>Contents</th>
</tr>
</thead>
<tbody>
<tr>
<td>Basic RAPID programming</td>
<td>Answers questions like &quot;Which instruction should I use?&quot; or &quot;What does this instruction mean?&quot;. This chapter briefly describes all instructions, functions, and data types grouped in accordance with the instruction pick-lists you use when programming. It also includes a summary of the syntax, which is particularly useful when programming offline. It also explains the inner details of the language.</td>
</tr>
<tr>
<td>Motion and I/O programming</td>
<td>This chapter describes the coordinate systems of the robot, its velocity and other motion characteristics during execution.</td>
</tr>
<tr>
<td>Glossary</td>
<td>A glossary to make things easier to understand.</td>
</tr>
</tbody>
</table>

How to read this manual

Typographic conventions

Examples of programs are always displayed in the same way as they are output to a file or printer. This differs from what is displayed on the FlexPendant in the following ways:

- Certain control words that are masked in the FlexPendant display are printed, for example words indicating the start and end of a routine.
- Data and routine declarations are printed in the formal form, for example `VAR num reg1;`.

In descriptions in this manual, all names of instructions, functions, and data types are written in monospace font, for example: `TPWrite`. Names of variables, system parameters, and options are written in italic font. Comments in example code are not translated (even if the manual is translated).

Syntax rules

Instructions and functions are described using both simplified syntax and formal syntax. If you use the FlexPendant to program, you generally only need to know the simplified syntax, since the robot automatically makes sure that the correct syntax is used.

Example of simplified syntax

This is an example of simplified syntax with the instruction `TPWrite`.

```
```

- Mandatory arguments are not enclosed in brackets.
- Optional arguments are enclosed in square brackets [ ]. These arguments can be omitted.
- Arguments that are mutually exclusive, that is cannot exist in the instruction at the same time, are separated by a vertical bar |.
- Arguments that can be repeated an arbitrary number of times are enclosed in curly brackets { }.

The above example uses the following arguments:

- `String` is a compulsory argument.
- `Num, Bool, Pos, Orient`, and `Dnum` are optional arguments.
- `Num, Bool, Pos, Orient`, and `Dnum` are mutually exclusive.

Example of formal syntax

```
TPWrite
[\String '':=' <expression (IN) of string>]
[\'\Num':=' <expression (IN) of num> ] |
[\'\Bool':=' <expression (IN) of bool> ] |
[\'\Pos':=' <expression (IN) of pos> ] |
[\'\Orient ':=' <expression (IN) of orient> ] |
[\'\ Dnum':=' <expression (IN) of dnum}';'
```

- The text within the square brackets [ ] may be omitted.

Continues on next page
Arguments that are mutually exclusive, that is cannot exist in the instruction at the same time, are separated by a vertical bar |.
Arguments that can be repeated an arbitrary number of times are enclosed in curly brackets { }.
Symbols that are written in order to obtain the correct syntax are enclosed in single quotation marks (apostrophes) '.
The data type of the argument and other characteristics are enclosed in angle brackets < >. See the description of the parameters of a routine for more detailed information.

The basic elements of the language and certain instructions are written using a special syntax, EBNF. This is based on the same rules, but with some additions.

- The symbol ::= means is defined as.
- Text enclosed in angle brackets < > is defined in a separate line.

Example

GOTO <identifier> ';'
<identifier> ::= <ident> | <ID>
<ident> ::= <letter> {<letter> | <digit> | '}'

Continued
1 Basic RAPID programming

1.1 Program structure

1.1.1 Introduction

Instructions
The program consists of a number of instructions which describe the work of the robot. Thus, there are specific instructions for the various commands, such as one to move the robot, one to set an output, etc.

The instructions generally have a number of associated arguments which define what is to take place in a specific instruction. For example, the instruction for resetting an output contains an argument which defines which output is to be reset; for example \texttt{Reset do5}. These arguments can be specified in one of the following ways:

- as a numeric value, for example \texttt{5} or \texttt{4.6}
- as a reference to data, for example \texttt{reg1}
- as an expression, for example \texttt{5+reg1*2}
- as a function call, for example \texttt{Abs(reg1)}
- as a string value, for example \texttt{"Producing part A"}

Routines
There are three types of routines – \textit{procedures, functions} and \textit{trap routines}.

- A procedure is used as a subprogram.
- A function returns a value of a specific type and is used as an argument of an instruction.
- Trap routines provide a means of responding to interrupts. A trap routine can be associated with a specific interrupt; for example when an input is set, it is automatically executed if that particular interrupt occurs.

Data
Information can also be stored in data, for example tool data (which contains all information on a tool, such as its TCP and weight) and numerical data (which can be used, for example, to count the number of parts to be processed). Data is grouped into different data types which describe different types of information, such as tools, positions and loads. As this data can be created and assigned arbitrary names, there is no limit (except that imposed by memory) on the number of data. These data can exist either globally in the program or locally within a routine.

There are three kinds of data – \textit{constants, variables} and \textit{persistents}.

- A constant represents a static value and can only be assigned a new value manually.
- A variable can also be assigned a new value during program execution.

Continues on next page
• A persistent can be described as a “persistent” variable. When a program is saved the initialization value reflects the current value of the persistent.

Other features

Other features in the language are:

• Routine parameters
• Arithmetic and logical expressions
• Automatic error handling
• Modular programs
• Multitasking

The language is not case sensitive, for example upper case and lower case letters are considered the same.
1.1.2 Basic elements

Identifiers

Identifiers are used to name modules, routines, data, and labels, for example:

```plaintext
MODULE module_name
PROC routine_name()
VAR pos data_name;
label_name:
```

Only characters in ISO 8859-1 are allowed.
The first character in an identifier must be a letter. The other characters can be letters, digits, or underscores (_).
The maximum length of any identifier is 32 characters, each of these characters being significant. Identifiers that are the same except that they are typed in the upper case, and vice versa, are considered the same.

Reserved words

The words listed below are reserved. They have a special meaning in the RAPID language and thus must not be used as identifiers.

There are also a number of predefined names for data types, system data, instructions, and functions, that must not be used as identifiers.

<table>
<thead>
<tr>
<th>ALIAS</th>

</tbody>
</table>

Spaces and new-line characters

The RAPID programming language is a free format language, meaning that spaces can be used anywhere except for in:

- identifiers
- reserved words
- numerical values

Continues on next page
1 Basic RAPID programming

1.1.2 Basic elements

Continued

- placeholders
New-line, tab and form-feed characters can be used wherever a space can be used, except for within comments.
Identifiers, reserved words, and numeric values must be separated from one another by a space, a new-line, tab, or form-feed character.

Numeric values

A numeric value can be expressed as:
- an integer, for example 3, -100, 3E2
- a decimal number, for example 3.5, -0.345, -245E-2
The value must be in the range specified by the ANSI IEEE 754 Standard for Floating-Point Arithmetic.

Logical values

A logical value can be expressed as TRUE or FALSE.

String values

A string value is a sequence of UTF-8 symbols and control characters (non-ISO 8859-1 (Latin-1)). Character codes can be included, making it possible to include non-printable characters (binary data) in the string as well. The string length can be maximum 80 bytes.
UTF-8 symbols are supported only in the following places:
- Comments in RAPID code
- Content in RAPID strings
Example:
"This is a string"
"This string ends with the BEL control character \07"
If a backslash (which indicates character code) or double quote character is included, it must be written twice.
Example:
"This string contains a " character"
"This string contains a \ character"

Comments

Comments are used to make the program easier to understand. They do not affect the meaning of the program in any way.
Comments use UTF-8 format, which means all symbols are supported, including symbols used in different languages, and emojis.
A comment starts with an exclamation mark (!) and ends with a new-line character.
It occupies the remainder of the line (starting from the exclamation mark) and cannot occur outside a module declaration.

! comment
IF reg1 > 5 THEN
! comment
reg2 := 0;

Continues on next page
Placeholders

Placeholders can be used to temporarily represent parts of a program that are not yet defined. A program that contains placeholders is syntactically correct and may be loaded into the program memory.

<table>
<thead>
<tr>
<th>Placeholder</th>
<th>Description</th>
</tr>
</thead>
<tbody>

</tbody>
</table>

File header

A program file can start with the following file header (it is not required):

```%%
VERSION:1
LANGUAGE:ENGLISH
%%
```

Syntax

Identifiers

```identifier ::= <ident> | <ID>
<ident ::= <letter> {<letter> | <digit> | '_'}
```

Numeric values

```num literal ::=  
<integer> [ <exponent> ]  
| <decimal integer> [ <exponent> ]  
| <hex integer> | <octal integer>  
| <binary integer>  
| <integer> '.' [ <integer> ] [ <exponent> ]  
| [ <integer> ] '.' <integer> [ <exponent> ]  
<integer> ::= <digit> {<digit>}  
<hex integer> ::= '0' ('X' | 'x')  
<hex digit> {<hex digit>}  
<octal integer> ::= '0' ('0' | 'o') <octal digit> {<octal digit>}
```
1 Basic RAPID programming

1.1.2 Basic elements

Continued

<binary integer> ::= '0' ('B' | 'b') <binary digit> (<binary digit>)
<exponent> ::= ('E' | 'e') ['+' | '-'] <integer>

digit ::= 0 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 | 9
<hex digit> ::= <digit> | A | B | C | D | E | F | a | b | c | d | e | f
<octal digit> ::= 0 | 1 | 2 | 3 | 4 | 5 | 6 | 7
<binary digit> ::= 0 | 1

Logical values

<bool literal> ::= TRUE | FALSE

String values

<string literal> ::= '"' {<character> | <character code> } '"'
<character code> ::= '\' <hex digit> <hex digit>
<hex digit> ::= <digit> | A | B | C | D | E | F | a | b | c | d | e | f

Comments

<comment> ::= '!' {<character> | <tab>} <newline>

| î | ñ | ò | ó | ô | õ | ö | ø
| ù | û | ü | ý | þ | ÿ
1.1.3 Modules

Introduction

The program is divided into program modules and system modules. The file format for a program module is .modx and for system module is .sysx.

Files in .mod or .sys format

In RobotWare 7.0 and earlier, the formats were .mod and .sys. To use these files in newer releases, the files must be converted, not just renamed. To convert a file manually, the file must be saved as UTF-8 without BOM (Byte Order Mark). When loading these in a RobotWare 7.1 controller or later using RobotStudio, they are automatically converted when saved.

Program modules

A program module can consist of different data and routines. Each module, or the whole program, can be copied to disk, etc., and vice versa.

One of the modules contains the entry procedure, a global procedure called Main. Executing the program means, in actual fact, executing the Main procedure. The program can include many modules, but only one of these will have a main procedure.

Continues on next page
A module may, for example, define the interface with external equipment or contain geometrical data that is either generated from CAD systems or created on-line by digitizing (teach programming).

Whereas small installations are often contained in one module, larger installations may have a main module that references routines and/or data contained in one or several other modules.

System modules

System modules are used to define common, system-specific data and routines, such as tools. They are not included when a program is saved, meaning that any update made to a system module will affect all existing programs currently in, or loaded at a later stage into the program memory.

Module declarations

A module declaration specifies the name and attributes of that module. These attributes can only be added off-line, not using the FlexPendant. The following are examples of the attributes of a module:

<table>
<thead>
<tr>
<th>Attribute</th>
<th>If specified</th>
</tr>
</thead>
<tbody>
<tr>
<td>SYSMODULE</td>
<td>The module is a system module, otherwise a program module</td>
</tr>
<tr>
<td>NOSTEPIN</td>
<td>The module cannot be entered during stepwise execution</td>
</tr>
<tr>
<td>VIEWONLY</td>
<td>The module cannot be modified</td>
</tr>
<tr>
<td>READONLY</td>
<td>The module cannot be modified, but the attribute can be removed</td>
</tr>
<tr>
<td>NOVIEW</td>
<td>The module cannot be viewed, only executed. Global routines can be reached from other modules and are always run as NOSTEPIN. The current values for global data can be reached from other modules or from the data window on the FlexPendant. NOVIEW can only be defined offline from a PC.</td>
</tr>
</tbody>
</table>

For example:

```
MODULE module_name (SYSMODULE, VIEWONLY)
!data type definition
!data declarations
!routine declarations
ENDMODULE
```

A module may not have the same name as another module or a global routine or data.

Program file structure

As indicated above all program modules are contained in a program with a specific program name. When saving a program, then a new directory is created with the name of the program. In this directory all program modules will be saved with a file extension .modx together with a description file with the same name as the program and with the extension .pgf. The description file will include a list of all modules contained in the program.
Syntax

Module declaration

```
<module declaration> ::= 
                      MODULE <module name> [ <module attribute list> ] 
                      <type definition list> 
                      <data declaration list> 
                      <routine declaration list> 
                      ENDMODULE 

<module name> ::= <identifier> 

<module attribute list> ::= '(' <module attribute> { ',' <module attribute> } ')' 

<module attribute> ::= 
                      SYSMODULE 
                      | NOVIEW 
                      | NOSTEPIN 
                      | VIEWONLY 
                      | READONLY 
```

Note

If two or more attributes are used they must be in the above order, the NOVIEW attribute can only be specified alone or together with the attribute SYSMODULE.

```
<type definition list> ::= { <type definition> } 
<data declaration list> ::= { <data declaration> } 
<routine declaration list> ::= { <routine declaration> } 
```
1.1.4 Predefined data

Introduction

In order to simplify programming, predefined data is supplied with the robot. This data does not have to be created and, consequently, can be used directly.

If this data is used, initial programming is made easier. It is, however, usually better to give your own names to the data you use, since this makes the program easier for you to read.

Contents

There are five numerical data (registers) and one clock predefined.

<table>
<thead>
<tr>
<th>Name</th>
<th>Data type</th>
<th>Declaration</th>
</tr>

<tr>
<td>clock1</td>
<td>clock</td>
<td>VAR clock clock1</td>
</tr>
</tbody>
</table>
1.1.5 Routines

Introduction

There are three types of routines (subprograms): procedures, functions, and traps.

- Procedures do not return a value and are used in the context of instructions.
- Functions return a value of a specific type and are used in the context of expressions.
- Trap routines provide a means of dealing with interrupts. A trap routine can be associated with a specific interrupt and then, if that particular interrupt occurs at a later stage, will automatically be executed. A trap routine can never be explicitly called from the program.

Routine scope

The scope of a routine denotes the area in which the routine is visible. The optional local directive of a routine declaration classifies a routine as local (within the module), otherwise it is global.

Example:

```
LOCAL PROC local_routine (...)
PROC global_routine (...)
```

The following scope rules apply to routines:

- The scope of a global routine may include any module in the task.
- The scope of a local routine comprises the module in which it is contained.
- Within its scope, a local routine hides any global routine or data with the same name.
- Within its scope, a routine hides instructions and predefined routines and data with the same name.

![Module Diagram]

In the example above, the following routines can be called from Routine h:

- Module1: Routine c, d.
- Module2: All routines.

A routine may not have the same name as another routine, data, or data type in the same module. A global routine may not have the same name as a module or a global routine, global data or global data type in another module.

Parameters

The parameter list of a routine declaration specifies the arguments (actual parameters) that must/can be supplied when the routine is called.

There are four different types of parameters (in the access mode):

- Normally, a parameter is used only as an input and is treated as a routine variable. Changing this variable will not change the corresponding argument.
- An **INOUT** parameter specifies that a corresponding argument must be a variable (entire, element or component) or an entire persistent which can be changed by the routine.
- A **VAR** parameter specifies that a corresponding argument must be a variable (entire, element or component) which can be changed by the routine.
- A **PERS** parameter specifies that a corresponding argument must be an entire persistent which can be changed by the routine.

If an **INOUT**, **VAR** or **PERS** parameter is updated, this means, in actual fact, that the argument itself is updated, that is it makes it possible to use arguments to return values to the calling routine.

Example:

```
PROC routine1 (num in_par, INOUT num inout_par,
                VAR num var_par, PERS num pers_par)
```

A parameter can be optional and may be omitted from the argument list of a routine call. An optional parameter is denoted by a backslash (\) before the parameter.

Example:

```
PROC routine2 (num required_par \num optional_par)
```

The value of an optional parameter that is omitted in a routine call may not be referenced. This means that routine calls must be checked for optional parameters before an optional parameter is used.

Two or more optional parameters may be mutually exclusive (that is declared to exclude each other), which means that only one of them may be present in a routine call. This is indicated by a stroke (pipe character, |) between the parameters in question.

Example:

```
PROC routine3 (\num exclude1 | num exclude2)
```

The special type, **switch**, may (only) be assigned to optional parameters and provides a means to use switch arguments, that is arguments that are only specified by names (not values). A value cannot be transferred to a **switch** parameter. The only way to use a **switch** parameter is to check for its presence using the predefined function, **Present**.

Example:

```
PROC routine4 (\switch on | switch off)
```

Arrays may be passed as arguments. The degree of an array argument must comply with the degree of the corresponding formal parameter. The dimension of an array
parameter is conformant (marked with *). The actual dimension thus depends on the dimension of the corresponding argument in a routine call. A routine can determine the actual dimension of a parameter using the predefined function, Dim.

Example:

```
PROC routine5 (VAR num pallet{*,*})
```

### Routine termination

The execution of a procedure is either explicitly terminated by a **RETURN** instruction or implicitly terminated when the end (ENDPROC, BACKWARD, ERROR, or UNDO) of the procedure is reached.

The evaluation of a function must be terminated by a **RETURN** instruction.

The execution of a trap routine is explicitly terminated using the **RETURN** instruction or implicitly terminated when the end (ENDTRAP, ERROR, or UNDO) of that trap routine is reached. Execution continues from the point where the interrupt occurred.

### Routine declarations

A routine can contain routine declarations (including parameters), data, a body, a backward handler (only procedures), an error handler, and an undo handler. Routine declarations cannot be nested, that is it is not possible to declare a routine within a routine.

### Module

```
Data declarations
Routine a
Routine b
Routine c
Routine d
Routine e
```

```
Routine declaration
Data declarations
Body (Instructions)
Backward handler
Error handler
Undo handler
```

### Procedure declaration

For example, multiply all elements in a num array by a factor:

```
PROC arrmul( VAR num array{*}, num factor)
    FOR index FROM 1 TO dim( array, 1 ) DO
        array{index} := array{index} * factor;
    ENDFOR
ENDPROC
```

### Function declaration

A function can return any data type value, but not an array value.
For example, return the length of a vector.

```rapid
FUNC num veclen (pos vector)
    RETURN Sqrt(Pow(vector.x,2)+Pow(vector.y,2)+Pow(vector.z,2));
ENDFUNC
```

Trap declaration

For example, respond to feeder empty interrupt:

```rapid
TRAP feeder_empty
    wait_feeder;
    RETURN;
ENDTRAP
```

Procedure call

When a procedure is called, the arguments that correspond to the parameters of the procedure shall be used:

- Mandatory parameters must be specified. They must also be specified in the correct order.
- Optional arguments can be omitted.
- Conditional arguments can be used to transfer parameters from one routine call to another.

See *Using function calls in expressions on page 40*.

The procedure name may either be statically specified by using an identifier (early binding) or evaluated during runtime from a string type expression (late binding). Even though early binding should be considered to be the normal procedure call form, late binding sometimes provides very efficient and compact code. Late binding is defined by putting percent signs before and after the string that denotes the name of the procedure.

**Example:**

```rapid
! early binding
TEST products_id
CASE 1:
    proc1 x, y, z;
CASE 2:
    proc2 x, y, z;
CASE 3:
    ...
! same example using late binding
% "proc" + NumToStr(product_id, 0) % x, y, z;
... 
! same example again using another variant of late binding
VAR string proccname {3} :=["proc1", "proc2", "proc3"];
...
% proccname(product_id) % x, y, z;
... 
```

Note that the late binding is available for procedure calls only, and not for function calls. If a reference is made to an unknown procedure using late binding, the system variable `ERRNO` is set to `ERR_REFUNKPRC`. If a reference is made to a procedure
call error (syntax, not procedure) using late binding, the system variable ERRNO is set to ERR_CALLPROC.

Syntax

Routine declaration

```
<routine declaration> ::= 
  [LOCAL] (<routine declaration> 
       | <function declaration> 
       | <trap declaration> ) 
  | <comment> 
  | <RDN>
```

Parameters

```
<parameter list> ::= 
  <first parameter declaration> { <next parameter declaration> } 
<first parameter declaration> ::= 
  <parameter declaration> 
  | <optional parameter declaration> 
  | <PAR>

<next parameter declaration> ::= 
  ',' <parameter declaration> 
  | <optional parameter declaration> 
  | ',' <optional parameter declaration> 
  | ',' <PAR>

<optional parameter declaration> ::= 
  '\' ( <parameter declaration> | <ALT> ) 
  ( '|' ( <parameter declaration> | <ALT> ) ) 
<parameter declaration> ::= 
  [ VAR | PERS | INOUT ] <data type> 
  <identifier> ['{ '*' { ',' '*' } }'] | <DIM> '}' 
  | 'switch' <identifier>
```

Procedure declaration

```
<precedure declaration> ::= 
  PROC <procedure name> 
  '(' [ <parameter list> ] ')' 
  <data declaration list> 
  <instruction list> 
  [ BACKWARD <instruction list> ] 
  [ ERROR <instruction list> ] 
  [ UNDO <instruction list> ] 
  ENDPROC
```

Function declaration

```
<function declaration> ::= 
  FUNC <value data type> 
  <function name> 
  '(' [ <parameter list> ] ')' 
  <data declaration list>
```

<optional procedure argument> ::= '\' <identifier> [ ':' ] <expression>

<conditional procedure argument> ::= '\' <identifier> '?' ( <parameter> | <VAR> )
1.2 Program data

1.2.1 Data types

Introduction

There are three different kinds of data types:

- An **atomic** type is atomic in the sense that it is not defined based on any other type and cannot be divided into parts or components, for example `num`.

- A **record** data type is a composite type with named, ordered components, for example `pos`. A component may be of an atomic or record type.

  A record value can be expressed using an aggregate representation, for example `[300, 500, depth]` pos record aggregate value.

  A specific component of a record data can be accessed by using the name of that component, for example `pos1.x := 300`; assignment of the x-component of `pos1`.

- An **alias** data type is by definition equal to another type. *Alias* types make it possible to classify data objects.

Non-value data types

Each available data type is either a **value** data type or a **non-value** data type. Simply speaking, a value data type represents some form of value. Non-value data cannot be used in value-oriented operations:

- Initialization
- Assignment (`:=`)
- Equal to (`=`) and not equal to (`<=>`) checks
- TEST instructions
- IN (access mode) parameters in routine calls
- Function (return) data types

The signal data types (`signalai`, `signaldi`, `signalgi`, `signalao`, `signaldo`, `signalgo`) are of the data type **semi value**. These data can be used in value-oriented operations, except initialization and assignment.

In the description of a data type it is only specified when it is a semi value or a non-value data type.

Equal (alias) data types

An **alias** data type is defined as being equal to another type. Data with the same data types can be substituted for one another.

Example:

```plaintext
VAR num level;
VAR dionum high:=1;
level:= high;

This is OK since dionum is an alias data type for num.
```

1.2.1 Data types

Continued

Syntax

<type definition>::=

[LOCAL] ( <record definition>
  | <alias definition> )
| <comment>
| <TDN>

<record definition>::=

RECORD <identifier>
  <record component list>
ENDRECORD

<record component list> ::=<record component definition> |
<record component definition> <record component list>

<record component definition> ::=<data type> <record component name> ';;'

<alias definition> ::=ALIAS <data type> <identifier> ';;'

<data type> ::= <identifier>
1.2.2 Data declarations

Introduction

There are three kinds of data:

• A **variable** can be assigned a new value during program execution.
• A **persistent** can be described as a persistent variable. This is accomplished
  by letting an update of the value of a persistent automatically cause the
  initialization value of the persistent declaration to be updated. (When a
  program is saved the initialization value of any persistent declaration reflects
  the current value of the persistent.)
• A **constant** represents a static value and cannot be assigned a new value.

A data declaration introduces data by associating a name (identifier) with a data

type. Except for predefined data and loop variables, all data used must be declared.

Data scope

The scope of data denotes the area in which the data is visible. The optional local
directive of a data declaration classifies data as local (within the module), otherwise
it is global. Note that the local directive may only be used at module level, not
inside a routine.

Example

```plaintext
LOCAL VAR num local_variable;
VAR num global_variable;
```

Program data

Data declared outside a routine is called **program data**. The following scope rules
apply to program data:

• The scope of predefined or global program data may include any module.
• The scope of local program data comprises the module in which it is
  contained.
• Within its scope, local program data hides any global data or routine with
  the same name (including instructions and predefined routines and data).

Program data may not have the same name as other data or a routine in the same
module. Global program data may not have the same name as other global data
or a routine in another module.

Routine data

Data declared inside a routine is called **routine data**. Note that the parameters of
a routine are also handled as routine data. The following scope rules apply to
routine data:

• The scope of routine data comprises the routine in which it is contained.
• Within its scope, routine data hides any other routine or data with the same
  name.

Routine data may not have the same name as other data or a label in the same
routine.

Continues on next page
Example

In this example, the following data can be called from routine e:

- Module1: Data c, d.
- Module2: Data a, f, g, e1.

The following data can be called from routine h:

- Module1: Data d.
- Module2: Data a, f, g, h1, c.

Module1

Local Data a
Local Data b
Data c
Data d
Data e

Module2

Local Data a
Local Data f
Data g
Local Routine e
Data e1
Routine h
Data h1
Data c

Variable declaration

A variable is introduced by a variable declaration and can be declared as global (no prescript needed) or local.

Example:

MainModule is loaded into task T_ROB1.

MODULE MainModule
!

VAR num global_var := 123;
!

LOCAL VAR num local_var := 789;
!

PROC main()
!

VAR num local_var2 := 321;
...

ENDPROC
ENDMODULE

A variable declared in a module that is installed shared can be declared with the prescript TASK, see Technical reference manual - System parameters, topic Controller, type Automatic Loading of Modules. Such a variable will be accessible
from all tasks but will have a unique value for each task. For example changing the variables value from one task will have no affect for other tasks.

Example:

```rapid
SharedModule is installed shared in the system.

MODULE SharedModule(SYSMODULE)
  ! This variable is accessible from all tasks, but has a
  ! unique value for each task.
  TASK VAR num global_var := 123;
  ...
ENDMODULE
```

Using the TASK prescript in a module that is not installed shared will have no effect.

Variables of any type can be given an array (of degree 1, 2 or 3) format by adding dimensional information to the declaration. A dimension is an integer value greater than 0.

Example:

```rapid
VAR pos pallet(14, 18);
```

Variables with value types may be initialized (given an initial value). The expression used to initialize a program variable must be constant. Note that the value of an uninitialized variable may be used, but it is undefined, that is set to zero if it is a num. A string is set to empty string, and a boolean is set to FALSE.

Example:

```rapid
VAR string author_name := "John Smith";
VAR pos start := [100, 100, 50];
VAR num maxno{10} := [1, 2, 3, 9, 8, 7, 6, 5, 4, 3];
```

The initialization value is set when:

- the program/module is loaded.
- the program pointer is reset, for example program pointer to main.

**Persistent declaration**

Persistents can only be declared at module level, not inside a routine. Persistents can be declared as system global (no prescript needed), task global, or local.

Example:

The following module is loaded into both T_ROB1 and T_ROB2.

```rapid
MODULE MainModule
  ! The scope of this persistent is within the task it’s been
  ! loaded to. But, it will share the current value with any
  ! other task declaring the same persistent. I.e. changing the
  ! value in T_ROB1 will automatically change the value in T_ROB2.
  PERS num globalpers := 123;

  ! The scope of this persistent is within the task this
  ! module has been loaded to.
  TASK PERS num taskpers := 456;

  ! The scope of this persistent is within this module.
  LOCAL PERS num localpers := 789;
ENDMODULE
```

Continues on next page
Local and task global persistents must be given an initialization value. For system global persistents the initial value may be omitted. The initialization value must be a single value (without data references or operands), or a single aggregate with members which, in turn, are single values or single aggregates.

Example:
```
PERS pos refpnt := [100.23, 778.55, 1183.98];
```
Persistents of any type can be given an array (of degree 1, 2 or 3) format by adding dimensional information to the declaration. A dimension is an integer value greater than 0.

Example:
```
PERS pos pallet(14, 18) := [...];
```
Note that if the current value of a persistent is changed, this causes the initialization value (if not omitted) of the persistent declaration to be updated. However, due to performance issues this update will not take place during program execution. The initial value will be updated when the module is saved (Backup, Save Module, Save Program). It will also be updated when editing program. The FlexPendant will always show the current value of the persistent.

Example:
```
PERS num reg1 := 0;
...
reg1 := 5;
```
After module save, if the code was executed, the saved module looks like this:
```
PERS num reg1 := 5;
...
reg1 := 5;
```

Constant declaration
A constant is introduced by a constant declaration. The value of a constant cannot be modified.

Example:
```
CONST num pi := 3.141592654;
```
A constant of any type can be given an array (of degree 1, 2 or 3) format by adding dimensional information to the declaration. A dimension is an integer value greater than 0.

```
CONST pos seq(3) := [[614, 778, 1020], [914, 998, 1021], [814, 998, 1022]];
```

Initiating data
The initialization value for a constant or variable can be a constant expression.
The initialization value for a persistent can only be a literal expression.

Example:
```
CONST num a := 2;
CONST num b := 3;
!Correct syntax
CONST num ab := a + b;
```
VAR num a_b := a + b;
PERS num a__b := 5; !
!Faulty syntax
PERS num a__b := a + b;

In the table below, you can see what is happening in various activities such as restart, new program, program start etc.

<table>

¹ Persistents without initial value is only initialized if not already declared.
² Generates an error when there is a semantic error in the actual task program.

Storage class

The storage class of a data object determines when the system allocates and de-allocates memory for the data object. The storage class of a data object is determined by the kind of data object and the context of its declaration and can be either static or volatile.

Constants, persistents, and module variables are static, that is they have the same storage during the lifetime of a task. This means that any value assigned to an persistent or a module variable, always remains unchanged until the next assignment.

Routine variables are volatile. The memory needed to store the value of a volatile variable is allocated first upon the call of the routine in which the declaration of the variable is contained. The memory is later de-allocated at the point of the return to the caller of the routine. This means that the value of a routine variable is always

Continues on next page
undefined before the call of the routine and is always lost (becomes undefined) at the end of the execution of the routine.

In a chain of recursive routine calls (a routine calling itself directly or indirectly) each instance of the routine receives its own memory location for the same routine variable - a number of instances of the same variable are created.

Syntax

Data declaration

<data declaration> ::= [LOCAL] ( <variable declaration>
| <persistent declaration>
| <constant declaration> )
| TASK <persistent declaration>
| <comment>
| <DDN>

Variable declaration

<variable declaration> ::= VAR <data type> <variable definition> ';
<variable definition> ::= <identifier> [ '{' <dim> { ',' <dim> } '}' ]
| ':=' <constant expression>
<dim> ::= <constant expression>

Persistent declaration

<persistent declaration> ::= PERS <data type> <persistent definition> ';
<persistent definition> ::= <identifier> [ '{' <dim> { ',' <dim> } '}' ]
| ':=' <literal expression>
<dim> ::= <constant expression>

Note

The literal expression may only be omitted for system global persistents.

Constant declaration

<constant declaration> ::= CONST <data type> <constant definition> ';
<constant definition> ::= <identifier> [ '{' <dim> { ',' <dim> } '}' ]
| ':=' <constant expression>
<dim> ::= <constant expression>
1.3 Expressions

1.3.1 Types of expressions

Description

An expression specifies the evaluation of a value. It can be used, for example:

- in an assignment instruction: for example: \( a := \frac{3b}{c} \);
- as a condition in an IF instruction: for example: \( \text{IF } a \geq 3 \text{ THEN } ... \);
- as an argument in an instruction: for example: \( \text{WaitTime time} \);
- as an argument in a function call: for example: \( a := \text{Abs}(3b) \);

Arithmetic expressions

An arithmetic expression is used to evaluate a numeric value.

Example:

\[ 2 \times \pi \times \text{radius} \]

### 1.3.1 Types of expressions

#### Logical expressions

A logical expression is used to evaluate a logical value (TRUE/FALSE).

Example:

```plaintext
a > 5 AND b = 3
```

<table>
<thead>
<tr>
<th>Operator</th>
<th>Operation</th>
<th>Operand types</th>
<th>Result type</th>
</tr>
</thead>
<tbody>
<tr>
<td>&lt;</td>
<td>less than</td>
<td>num &lt; num</td>
<td>bool</td>
</tr>
<tr>
<td>&lt;=</td>
<td>less than or equal to</td>
<td>num &lt;= num</td>
<td>bool</td>
</tr>
<tr>
<td>=</td>
<td>equal to</td>
<td>any = any</td>
<td>bool</td>
</tr>
<tr>
<td>&gt;=</td>
<td>greater than or equal to</td>
<td>num &gt;= num</td>
<td>bool</td>
</tr>
<tr>
<td>&gt;</td>
<td>greater than</td>
<td>num &gt; num</td>
<td>bool</td>
</tr>
<tr>
<td>&lt;&gt;</td>
<td>not equal to</td>
<td>any &lt;&gt; any</td>
<td>bool</td>
</tr>
<tr>
<td>AND</td>
<td>and</td>
<td>bool AND bool</td>
<td>bool</td>
</tr>
<tr>
<td>XOR</td>
<td>exclusive or</td>
<td>bool XOR bool</td>
<td>bool</td>
</tr>
<tr>
<td>OR</td>
<td>or</td>
<td>bool OR bool</td>
<td>bool</td>
</tr>
<tr>
<td>NOT</td>
<td>unary not; negation</td>
<td>NOT bool</td>
<td>bool</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Operator</th>
<th>Operation</th>
<th>Operand types</th>
<th>Result type</th>
</tr>
</thead>
<tbody>
<tr>
<td>MOD</td>
<td>integer modulo; remainder</td>
<td>dnum MOD dnum</td>
<td>dnum</td>
</tr>
</tbody>
</table>

- **i** Preserves integer (exact) representation as long as operands and result are kept within the integer sub-domain of the numerical type.
- **ii** The result receives the same type as the operand. If the operand has an alias data type, the result receives the alias "base" type (num, dnum or pos).
- **iii** Integer operations, for example 14 DIV 4 = 3, 14 MOD 4 = 2. (Non-integer operands are illegal.)
String expressions

A string expression is used to carry out operations on strings.

Example: "IN" + "PUT" gives the result "INPUT"

<table>
<thead>
<tr>
<th>Operator</th>
<th>Operation</th>
<th>Operand types</th>
<th>Result type</th>
</tr>
</thead>
<tbody>
<tr>
<td>+</td>
<td>string concatenation</td>
<td>string + string</td>
<td>string</td>
</tr>
</tbody>
</table>
1.3.2 Using data in expressions

Introduction
An entire variable, persistent or constant can be a part of an expression.

Example:
\[ 2\pi r \]

Arrays

A variable, persistent or constant declared as an array can be referenced to the whole array or a single element.

An array element is referenced using the index number of the element. The index is an integer value greater than 0 and may not violate the declared dimension. Index value 1 selects the first element. The number of elements in the index list must fit the declared degree (1, 2 or 3) of the array.

Example:
```rapid
VAR num row{3};
VAR num column{3};
VAR num value;

! get one element from the array
value := column{3};

! get all elements in the array
row := column;
```

Records

A variable, persistent or constant declared as a record can be referenced to the whole record or a single component.

A record component is referenced using the component name.

Example:
```rapid
VAR pos home;
VAR pos pos1;
VAR num yvalue;
...
! get the Y component only
yvalue := home.y;

! get the whole position
pos1 := home;
```
1.3.3 Using aggregates in expressions

Introduction

An aggregate is used for record or array values.

Example:

! pos record aggregate
pos := \([x, y, 2*x]\);

! pos array aggregate
posarr := \([0, 0, 100], [0,0,z]\);

Prerequisites

It must be possible to determine the data type of an aggregate the context. The data type of each aggregate member must be equal to the type of the corresponding member of the determined type.

Example (aggregate type pos - determined by p1):

VAR pos pl;
pl :=\([1, -100, 12]\);

Example of what is not allowed (not allowed since the data type of neither of the aggregates can be determined by the context):

VAR pos pl;
IF \([1, -100, 12] = [a,b,b]\) THEN
1.3.4 Using function calls in expressions

Introduction

A function call initiates the evaluation of a specific function and receives the value returned by the function.

Example:

\[ \text{Sin}(\text{angle}) \]

Arguments

The arguments of a function call are used to transfer data to (and possibly from) the called function. The data type of an argument must be equal to the type of the corresponding parameter of the function. Optional arguments may be omitted but the order of the (present) arguments must be the same as the order of the formal parameters. In addition, two or more optional arguments may be declared to exclude each other, in which case, only one of them may be present in the argument list.

A required (compulsory) argument is separated from the preceding argument by a comma (,). The formal parameter name may be included or omitted.

<table>
<thead>
<tr>
<th>Example</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>\text{Polar}(3.937, 0.785398)</td>
<td>Two required arguments, without or with the parameter name.</td>
</tr>
<tr>
<td>\text{Polar}(\text{Dist}=3.937, \text{Angle}=0.785398)</td>
<td></td>
</tr>
<tr>
<td>\text{Cosine}(45)</td>
<td>One required argument, without or with one switch.</td>
</tr>
<tr>
<td>\text{Cosine}(0.785398\text{Rad})</td>
<td></td>
</tr>
<tr>
<td>\text{Dist}(p2)</td>
<td>One required argument, without or with one optional argument.</td>
</tr>
<tr>
<td>\text{Dist}(\text{distance}:=\text{pos1}, p2)</td>
<td></td>
</tr>
</tbody>
</table>

An optional argument must be preceded by a backslash (\) and the formal parameter name. A switch type argument is somewhat special; it may not include any argument expression. Instead, such an argument can only be either present or not present.

Conditional arguments are used to support smooth propagation of optional arguments through chains of routine calls. A conditional argument is considered to be present if the specified optional parameter (of the calling function) is present, otherwise it is simply considered to be omitted. Note that the specified parameter must be optional.

Example:

\[
\text{PROC Read_from_file (iodev File \num Maxtime)} \\
\ldots \\
\text{character}:=\text{ReadBin (File \Time?Maxtime)}; \\
! Max. time is only used if specified when calling the routine \\
! \text{Read_from_file} \\
\ldots \\
\text{ENDPROC}
\]

Continues on next page
Parameters

The parameter list of a function assigns an access mode to each parameter. The access mode can be either in, inout, var, or pers:

- An **IN** parameter (default) allows the argument to be any expression. The called function views the parameter as a constant.
- An **INOUT** parameter requires the corresponding argument to be a variable (entire, array element or record component) or an entire persistent. The called function gains full (read/write) access to the argument.
- A **VAR** parameter requires the corresponding argument to be a variable (entire, array element or record component). The called function gains full (read/write) access to the argument.
- A **PERS** parameter requires the corresponding argument to be an entire persistent. The called function gains full (read/update) access to the argument.
Priority rules

The relative priority of the operators determines the order in which they are evaluated. Parentheses provide a means to override operator priority. The rules below imply the following operator priority:

<table>
<thead>
<tr>
<th>Priority</th>
<th>Operators</th>
</tr>
</thead>
<tbody>
<tr>
<td>Highest</td>
<td>* / DIV MOD</td>
</tr>
<tr>
<td></td>
<td>+ -</td>
</tr>
<tr>
<td></td>
<td>&lt; &gt; &lt;&gt; &lt;= &gt;= =</td>
</tr>
<tr>
<td></td>
<td>AND</td>
</tr>
<tr>
<td>Lowest</td>
<td>XOR OR NOT</td>
</tr>
</tbody>
</table>

An operator with high priority is evaluated prior to an operator with low priority. Operators of the same priority are evaluated from left to right.

<table>
<thead>
<tr>
<th>Example expression</th>
<th>Evaluation order</th>
<th>Comment</th>
</tr>
</thead>
<tbody>
<tr>
<td>a + b + c</td>
<td>(a + b) + c</td>
<td>Left to right rule</td>
</tr>
<tr>
<td>a + b * c</td>
<td>a + (b * c)</td>
<td>* higher than +</td>
</tr>
<tr>
<td>a OR b OR c</td>
<td>(a OR b) OR c</td>
<td>Left to right rule</td>
</tr>
<tr>
<td>a AND b OR c AND d</td>
<td>(a AND b) OR (c AND d)</td>
<td>AND higher than OR</td>
</tr>
<tr>
<td>a &lt; b AND c &lt; d</td>
<td>(a &lt; b) AND (c &lt; d)</td>
<td>&lt; higher than AND</td>
</tr>
</tbody>
</table>

1.4 Instructions

Description

Instructions are executed in succession unless a program flow instruction or an interrupt or error causes the execution to continue at some other place.

Most instructions are terminated by a semicolon (;). A label is terminated by a colon (:). Some instructions may contain other instructions and are terminated by specific keywords.

<table>
<thead>
<tr>
<th>Instruction</th>
<th>Termination word</th>
</tr>
</thead>
<tbody>
<tr>
<td>IF</td>
<td>ENDF</td>
</tr>
<tr>
<td>FOR</td>
<td>ENDFOR</td>
</tr>
<tr>
<td>WHILE</td>
<td>ENDFOR</td>
</tr>
<tr>
<td>TEST</td>
<td>ENDFOR</td>
</tr>
</tbody>
</table>

Example:

```plaintext
WHILE index < 100 DO
  index := index + 1;
ENDWHILE
```

Pick lists

All instructions are collected into specific groups, which are described in the following sections. This grouping is the same as can be found in the pick lists used when adding new instructions to a program on the FlexPendant.

Syntax

```plaintext
<instruction list> ::= { <instruction> }
<instruction> ::= 
  {<instruction according to separate chapter in this manual>}
  <SMT>
```
1.5 Controlling the program flow

Introduction

The program is executed sequentially as a rule, that is instruction by instruction. Sometimes, instructions which interrupt this sequential execution and call another instruction are required to handle different situations that may arise during execution.

Programming principles

The program flow can be controlled according to five different principles:

- By calling another routine (procedure) and, when that routine has been executed, continuing execution with the instruction following the routine call.
- By executing different instructions depending on whether or not a given condition is satisfied.
- By repeating a sequence of instructions a number of times or until a given condition is satisfied.
- By going to a label within the same routine.
- By stopping program execution.

Calling another routine

<table>
<thead>
<tr>

1.6 Various instructions

1.6 Various instructions

Introduction

Various instructions are used to

- assign values to data
- wait a given amount of time or wait until a condition is satisfied
- insert a comment into the program
- load program modules.

Assigning a value to data

Data can be assigned an arbitrary value. It can, for example, be initialized with a constant value, for example 5, or updated with an arithmetic expression, for example \( \text{reg1} + 5 \times \text{reg3} \).

<table>
<thead>
<tr>
<th>Instruction</th>
<th>Used to</th>
</tr>
</thead>
<tbody>
<tr>
<td>:=</td>
<td>Assign a value to data</td>
</tr>
</tbody>
</table>

Wait

The robot can be programmed to wait a given amount of time, or to wait until an arbitrary condition is satisfied; for example, to wait until an input is set.

<table>
<thead>
<tr>
<th>Instruction</th>
<th>Used to</th>
</tr>
</thead>
<tbody>
<tr>
<td>( \text{WaitTime} )</td>
<td>Wait a given amount of time or to wait until the robot stops moving</td>
</tr>
<tr>
<td>( \text{WaitUntil} )</td>
<td>Wait until a condition is satisfied</td>
</tr>
<tr>
<td>( \text{WaitDI} )</td>
<td>Wait until a digital input is set</td>
</tr>
<tr>
<td>( \text{WaitDO} )</td>
<td>Wait until a digital output is set</td>
</tr>
</tbody>
</table>

Comments

Comments are only inserted into the program to increase its readability. Program execution is not affected by a comment.

<table>
<thead>
<tr>
<th>Instruction</th>
<th>Used to</th>
</tr>
</thead>
<tbody>
<tr>
<td>!</td>
<td>Comment on the program. A line starting with ! (exclamation mark) is a comment and is discarded by the program execution.</td>
</tr>
</tbody>
</table>

Loading program modules

Program modules can be loaded from mass memory or erased from the program memory. In this way large programs can be handled with only a small memory.

<table>
<thead>
<tr>
<th>Instruction</th>
<th>Used to</th>
</tr>
</thead>
<tbody>
<tr>
<td>( \text{Load} )</td>

</table>
1.7 Motion settings

**Introduction**

Some of the motion characteristics of the robot are determined using logical instructions that apply to all movements:

- Maximum TCP speed
- Maximum velocity and velocity override
- Acceleration
- Management of different robot configurations
- Payload
- Behavior close to singular points
- Program displacement
- Soft servo
- Tuning values
- Activation and deactivation of event buffer
- Suppress corner path warnings

**Programming principles**

The basic characteristics of the robot motion are determined by data specified for each positioning instruction. Some data, however, is specified in separate instructions which apply to all movements until that data changes.

The general motion settings are specified using a number of instructions, but can also be read using the system variable `C_MOTSET` or `C_PROGDISP`.

Default values are automatically set (by executing the routine `SYS_RESET` in system module `BASE_SHARED`)

- when using the restart mode `Reset system`,
- when a new program is loaded,
- when the program is started from the beginning.

**Maximum TCP speed Function**

<table>
<thead>
<tr>
<th>Function</th>
<th>Used to</th>
</tr>
</thead>
<tbody>
<tr>
<td>MaxRobSpeed</td>
<td>Return the maximum TCP speed for the used robot type</td>
</tr>
</tbody>
</table>

**Defining velocity**

The absolute velocity is programmed as an argument in the positioning instruction. In addition to this, the maximum velocity and velocity override (a percentage of the programmed velocity) can be defined.

A limitation of the speed can also be set, and it is later on limited when a system input signal is set.

<table>
<thead>
<tr>
<th>Instruction</th>
<th>Used to define</th>
</tr>
</thead>
<tbody>
<tr>
<td>VelSet</td>
<td>The maximum velocity and velocity override</td>
</tr>
<tr>
<td>SpeedRefresh</td>
<td>Update speed override for ongoing movement</td>
</tr>
</tbody>
</table>

Continues on next page
### Defining acceleration

When fragile parts, for example, are handled, the acceleration can be reduced for part of the program.

<table>
<thead>
<tr>
<th>Instruction</th>
<th>Used to</th>
</tr>
</thead>
<tbody>
<tr>
<td>SpeedLimAxis</td>
<td>Set speed limitation for an axis. It is later on applied by a system input signal.</td>
</tr>
<tr>
<td>SpeedLimCheckPoint</td>
<td>Set speed limitation for check points. It is later on applied by a system input signal.</td>
</tr>
</tbody>
</table>

### Defining configuration management

The robot's configuration is normally checked during motion. If joint (axis-by-axis) motion is used, the correct configuration will be achieved. If linear or circular motion are used, the robot will always move towards the closest configuration, but a check is performed to see if it is the same as the programmed one. It is possible to change this, however.

<table>
<thead>
<tr>
<th>Instruction</th>
<th>Used to</th>
</tr>
</thead>
<tbody>
<tr>
<td>ConfJ</td>
<td>Configuration control on/off during joint motion</td>
</tr>
<tr>
<td>ConfL</td>
<td>Configuration check on/off during linear motion</td>
</tr>
</tbody>
</table>

### Defining the payload

To achieve the best robot performance, the correct payload must be defined.

<table>
<thead>
<tr>
<th>Instruction</th>
<th>Used to define</th>
</tr>
</thead>
<tbody>
<tr>
<td>GripLoad</td>
<td>Define the payload of the gripper</td>
</tr>
</tbody>
</table>

### Defining the behavior near singular points

The robot can be programmed to avoid singular points by changing the tool orientation automatically.

<table>
<thead>
<tr>
<th>Instruction</th>
<th>Used to define</th>
</tr>
</thead>
<tbody>
<tr>
<td>SingArea</td>
<td>Define the interpolation method through singular points</td>
</tr>
</tbody>
</table>

### Activation and deactivation of event buffer

To achieve the best robot performance and good application behavior when combining an application using finepoints and a continous application where signals needs to be set in advance due to slow process equipment, the event buffer can be activated and deactivated.

<table>
<thead>
<tr>
<th>Instruction</th>
<th>Used to define</th>
</tr>
</thead>
<tbody>
<tr>
<td>ActEventBuffer</td>
<td>Activate the configured event buffer</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Instruction</th>
<th>Used to define</th>
</tr>
</thead>
<tbody>
<tr>
<td>DeactEventBuffer</td>
<td>Deactivate the use of the event buffer</td>
</tr>
</tbody>
</table>

**Suppress corner path warnings**

To avoid warning messages on the FlexPendant when a corner path failure occurs, these warnings can be activated and deactivated.

<table>
<thead>
<tr>
<th>Instruction</th>
<th>Used to define</th>
</tr>
</thead>
<tbody>
<tr>
<td>CornerPathWarning TRUE;</td>
<td>Suppress corner path warnings</td>
</tr>
<tr>
<td>CornerPathWarning FALSE;</td>
<td>Enable corner path warnings</td>
</tr>
</tbody>
</table>

**Displacing a program**

When part of the program must be displaced, for example following a search, a program displacement can be added.

<table>
<thead>
<tr>
<th>Instruction</th>
<th>Used to</th>
</tr>
</thead>
<tbody>
<tr>
<td>PDispOn</td>
<td>Activate program displacement</td>
</tr>
<tr>
<td>PDispSet</td>
<td>Activate program displacement by specifying a value</td>

</thead>
<tbody>
<tr>
<td>DefDFrame</td>
<td>Calculate a program displacement from three positions</td>
</tr>
<tr>
<td>DefFrame</td>
<td>Calculate a program displacement from six positions</td>
</tr>
<tr>
<td>ORobT</td>
<td>Remove program displacement from a position</td>
</tr>
<tr>
<td>DefAccFrame</td>
<td>Define a frame from original positions and displaced positions</td>
</tr>
</tbody>
</table>

**Soft servo**

One or more of the robot axes can be made “soft”. When using this function, the robot will be compliant and can replace, for example, a spring tool.

<table>
<thead>
<tr>
<th>Instruction</th>
<th>Used to</th>
</tr>
</thead>
<tbody>
<tr>
<td>SoftAct</td>
<td>Activate the soft servo for one or more axes</td>
</tr>
<tr>
<td>SoftDeact</td>
<td>Deactivate the soft servo</td>
</tr>
</tbody>
</table>

**Adjust the robot tuning values**

In general, the performance of the robot is self-optimising; however, in certain extreme cases, overrunning, for example, can occur. You can adjust the robot tuning values to obtain the required performance.

<table>
<thead>
<tr>
<th>Instruction</th>
<th>Used to</th>
</tr>
</thead>
<tbody>
<tr>
<td>TuneServo</td>
<td>Adjust the robot tuning values</td>
</tr>
</tbody>
</table>
### 1.7 Motion settings

#### World zones

Up to 10 different volumes can be defined within the working area of the robot. These can be used for:
- Indicating that the robot’s TCP is a definite part of the working area.
- Delimiting the working area for the robot and preventing a collision with the tool.
- Creating a working area common to two robots. The working area is then available only to one robot at a time.

The instructions in the table below are only available when the robot is equipped with the option *World Zones*.

<table>

--- | ---
progdisp | Program displacement
1.8 Motion

Principle for robot movement
The robot movements are programmed as pose-to-pose movements, that is move from the current position to a new position. The path between these two positions is then automatically calculated by the robot.

Programming principles
The basic motion characteristics, such as the type of path, are specified by choosing the appropriate positioning instruction. The remaining motion characteristics are specified by defining data which are arguments of the instruction.

- Position data (end position for robot and additional axes)
- Speed data (desired speed)
- Zone data (position accuracy)
- Tool data (for example the position of the TCP)
- Work object data (for example the current coordinate system)

Some of the motion characteristics of the robot are determined using logical instructions which apply to all movements (see Motion settings on page 50):

- Maximum velocity and velocity override
- Acceleration
- Management of different robot configurations
- Payload
- Behavior close to singular points
- Program displacement
- Soft servo
- Tuning values
- Activation and deactivation of event buffer

Both the robot and the additional axes are positioned using the same instructions. The additional axes are moved at a constant velocity, arriving at the end position at the same time as the robot.

Positioning instructions

<table>
<thead>

<td>Moves the robot linearly and executes a RAPID procedure.</td>
</tr>
</tbody>
</table>

#### Searching

During the movement, the robot can search for the position of a work object, for example. The searched position (indicated by a sensor signal) is stored and can be used later to position the robot or to calculate a program displacement.

<table>
<thead>
<tr>
<th>Instruction</th>
<th>Type of movement</th>
</tr>
</thead>
<tbody>
<tr>
<td>SearchC</td>
<td>TCP along a circular path.</td>
</tr>
<tr>

</tr>
</tbody>
</table>

#### Activating outputs or interrupts at specific positions

Normally, logical instructions are executed in the transition from one positioning instruction to another. If, however, special motion instructions are used, these can be executed instead when the robot is at a specific position.

<table>
<thead>
<tr>
<th>Instruction</th>
<th>Used to</th>
</tr>
</thead>
<tbody>
<tr>
<td>TriggC</td>
<td>Run the robot (TCP) circularly with an activated trigg condition.</td>

<table>
<thead>
<tr>
<th>Function</th>
<th>Used to</th>
</tr>
</thead>
<tbody>
<tr>
<td>GetMotorTorque</td>
<td>Read the current torque of the robot and external axes motors, and can be used to detect if a servo gripper holds a load or not.</td>
</tr>
<tr>
<td>getNextMechUnit</td>
<td>Retrieve the name and data for mechanical units</td>
</tr>
<tr>
<td>IsMechUnitActive</td>
<td>Check whether a mechanical unit is activated or not</td>
</tr>
</tbody>
</table>

### Independent axes

The robot axis 6 (and 4 on IRB 1600, 2600 and 4600 except ID versions) or an additional axis can be moved independently of other movements. The working area of an axis can also be reset, which will reduce the cycle times.

The instructions in the table below are only available when the robot is equipped with the option *Independent Axis*.

<table>
<thead>
<tr>
<th>Instruction</th>
<th>Used to</th>
</tr>
</thead>
<tbody>
<tr>
<td>IndAMove</td>

1.9 Input and output signals

Signals

The robot can be equipped with a number of digital and analog user signals that can be read and changed from within the program.

Programming principles

The signal names are defined in the system parameters. These names are always available in the program for reading or setting I/O operations.

The value of an analog signal, a digital signal, or a group of digital signals is specified as a numeric value. For an analog signal and a digital signal the numeric value is of the type `num`. For a digital group signal the numeric value is of the type `dnum`.

Changing the value of a signal

<table>
<thead>
<tr>
<th>Instruction</th>
<th>Used to define</th>
</tr>
</thead>
<tbody>
<tr>
<td>InvertDO</td>
<td>Invert the value of a digital output signal</td>
</tr>
<tr>
<td>PulseDO</td>
<td>Generate a pulse on a digital output signal</td>
</tr>
<tr>
<td>Reset</td>
<td>Reset a digital output signal (to 0)</td>
</tr>
<tr>
<td>Set</td>
<td>Set a digital output signal (to 1)</td>
</tr>
<tr>
<td>SetAO</td>
<td>Change the value of an analog output signal</td>
</tr>
<tr>
<td>SetDO</td>
<td>Change the value of a digital output signal (symbolic value; for example high/low)</td>
</tr>
<tr>
<td>SetGO</td>
<td>Change the value of a group of digital output signals</td>
</tr>
</tbody>
</table>

Reading the value of input signals

The value of an input signal can be read directly in the program, for example:

```plaintext
VAR num mynum;
VAR dnum mydnum;
! Digital input
IF di1 = 1 THEN ...
mynum:=di1;
! Digital group input
IF gi1 = 5 THEN ...
mydnum:=gi1;
! Analog input
IF ai1 > 5.2 THEN ...
mynum:=ai1;
```

The following recoverable errors can be generated. The errors can be handled in an error handler. The system variable ERRNO will be set to:

- `ERR_NO_ALIASIO_DEF` if the signal variable is a variable declared in RAPID. It has not been connected to an I/O signal defined in the I/O configuration with instruction AliasIO.
- `ERR_NORUNUNIT` if there is no contact with the I/O unit.

Continues on next page
ERR_SIG_NOT_VALID if the I/O signal cannot be accessed (only valid for ICI fieldbus).

Reading the value of output signals
The value of an output signal can be read directly in the program, for example:

! Digital output
IF do1 = 1 THEN ...  
! Digital group output
IF go1 = 5 THEN ...  
! Analog output
IF ao1 > 5.2 THEN ...

The following recoverable errors can be generated. The errors can be handled in an error handler. The system variable ERRNO will be set to:

ERR_NO_ALIASIO_DEF if the signal variable is a variable declared in RAPID. It has not been connected to an I/O signal defined in the I/O configuration with instruction AliasIO.

ERR_NORUNUNIT if there is no contact with the I/O unit.

ERR_SIG_NOT_VALID if the I/O signal cannot be accessed (only valid for ICI fieldbus).

Testing input or output signals

<th>Used to define</th>
</tr>
</thead>
<tbody>
<tr>
<td>GetGroupSignalInfo</td>
<td>Read information about a digital group signal.</td>
</tr>
</tbody>
</table>
1.10 Communication

Communicating via I/O devices and files

There are four possible ways to communicate via I/O devices and files:

- Messages can be output to the FlexPendant display and the user can answer questions, such as about the number of parts to be processed.
- Character-based information can be written to or read from text files in mass memory. In this way, for example, production statistics can be stored and processed later in a PC. Information can also be printed directly on a printer connected to the robot.
- Binary information can be transferred between the robot and a sensor, for example.
- Binary information can be transferred between the robot and another computer, for example, with a link protocol.

Programming principles

The decision whether to use character-based or binary information depends on how the equipment with which the robot communicates handles that information. A file, for example, can have data that is stored in character-based or binary form.

If communication is required in both directions simultaneously, binary transmission is necessary.

Each I/O device or file used must first be opened. On doing this, the device/file receives a descriptor that is then used as a reference when reading/writing. The FlexPendant can be used at all times and does not need to be opened.

Both text and the value of certain types of data can be printed.

Communicating using the FlexPendant, function group TP

<table>
<thead>
<tr>

1.11 Interrupts

Introduction

Interrupts are program-defined events, identified by interrupt numbers. An interrupt occurs when an interrupt condition is true. Unlike errors, the occurrence of an interrupt is not directly related to (synchronous with) a specific code position. The occurrence of an interrupt causes suspension of the normal program execution and control is passed to a trap routine.

Even though the robot immediately recognizes the occurrence of an interrupt (only delayed by the speed of the hardware), its response – calling the corresponding trap routine – can only take place at specific program positions, namely:

- when the next instruction is entered,
- any time during the execution of a waiting instruction, for example WaitUntil,
- any time during the execution of a movement instruction, for example MoveL.

This normally results in a delay of 2-30 ms between interrupt recognition and response, depending on what type of movement is being performed at the time of the interrupt.

The raising of interrupts may be disabled and enabled. If interrupts are disabled, any interrupt that occurs is queued and not raised until interrupts are enabled again. Note that the interrupt queue may contain more than one waiting interrupt. Queued interrupts are raised in FIFO order (first in, first out). Interrupts are always disabled during the execution of a trap routine.

When running stepwise and when the program has been stopped, no interrupts will be handled. Interrupts in queue at stop will be thrown away and any interrupts generated under stop will not be dealt, except for safe interrupts, see Safe Interrupt on page 72.

The maximum number of defined interrupts at any one time is limited to 100 per program task.

Programming principles

Each interrupt is assigned an interrupt identity. It obtains its identity by creating a variable (of data type intnum) and connecting this to a trap routine.

The interrupt identity (variable) is then used to order an interrupt, that is to specify the reason for the interrupt. This may be one of the following events:

- An input or output is set to one or to zero.
- A given amount of time elapses after an interrupt is ordered.
- A specific position is reached.

When an interrupt is ordered, it is also automatically enabled, but can be temporarily disabled. This can take place in two ways:

- All interrupts can be disabled. Any interrupts occurring during this time are placed in a queue and then automatically generated when interrupts are enabled again.
• Individual interrupts can be deactivated. Any interrupts occurring during this time are disregarded.

### Data type of interrupts

<table>
<thead>
<tr>
<th>Data type</th>
<th>Used to</th>
</tr>
</thead>
<tbody>
<tr>
<td>intnum</td>
<td>Define the identity of an interrupt.</td>
</tr>
<tr>
<td>trapdata</td>
<td>Contain the interrupt data that caused the current TRAP routine to be executed.</td>
</tr>
<tr>
<td>errtype</td>
<td>Specify an error type (gravity)</td>
</tr>
<tr>
<td>errdomain</td>
<td>Order and enable an interrupt when an error occurs.</td>
</tr>
</tbody>
</table>

### Safe Interrupt

Some instructions, for example ITimer and ISignalDI, can be used together with Safe Interrupt. Safe Interrupts are interrupts that will be queued if they arrive during stop or stepwise execution. The queued interrupts will be dealt with as soon as continuous execution is started, they will be handled in FIFO order. Interrupts in queue at stop will also be dealt with. The instruction ISleep can not be used together with safe interrupts.

### Interrupt manipulation

Defining an interrupt makes it known to the system. The definition specifies the interrupt condition and activates and enables the interrupt.

Example:

```plaintext
VAR intnum sigint;
ISignalDI di1, high, sigint;
```

An activated interrupt may in turn be deactivated (and vice versa).

During the deactivation time, any generated interrupts of the specified type are thrown away without any trap execution.

Example:

```plaintext
! deactivate
ISleep sigint;

! activate
IWatch sigint;
```

An enabled interrupt may in turn be disabled (and vice versa).

During the disable time, any generated interrupts of the specified type are queued and raised first when the interrupts are enabled again.

Example:

```plaintext
! disable
IDisable sigint;

! enable
IEnable sigint;
```

Deleting an interrupt removes its definition. It is not necessary to explicitly remove an interrupt definition, but a new interrupt cannot be defined to an interrupt variable until the previous definition has been deleted.

Continues on next page
Example:
IDelete siglint;

Trap routines

Trap routines provide a means of dealing with interrupts. A trap routine can be connected to a particular interrupt using the CONNECT instruction. When an interrupt occurs, control is immediately transferred to the associated trap routine (if any). If an interrupt occurs, that does not have any connected trap routine, this is treated as a fatal error, that is causes immediate termination of program execution.

Example:

VAR intnum empty;
VAR intnum full;
PROC main()
    ! Connect trap routines
    CONNECT empty WITH etrap;
    CONNECT full WITH ftrap;
    ! Define feeder interrupts
    ISignalDI di1, high, empty;
    ISignalDI di3, high, full;
    ...
    ! Delete interrupts
    IDelete empty;
    IDelete full;
ENDPROC
    ! Responds to “feeder empty” interrupt
    TRAP etrap
        open_valve;
        RETURN;
    ENDRAP
    ! Responds to “feeder full” interrupt
    TRAP ftrap
        close_valve;
        RETURN;
    ENDRAP

Several interrupts may be connected to the same trap routine. The system variable INTNO contains the interrupt number and can be used by a trap routine to identify an interrupt. After the necessary action has been taken, a trap routine can be terminated using the RETURN instruction or when the end (ENDTRAP or ERROR) of the trap routine is reached. Execution continues from the place where the interrupt occurred.
1.12 Error recovery

Introduction

Many of the errors that occur when a program is being executed can be handled in the program, which means that program execution does not have to be interrupted. These errors are either of a type detected by the system, such as division by zero, or of a type that is raised by the program, such as a program raising an error when an incorrect value is read by a bar code reader.

An execution error is an abnormal situation, related to the execution of a specific piece of a program. An error makes further execution impossible (or at least hazardous). Overflow and division by zero are examples of errors.

Error numbers

Errors are identified by their unique error number and are always recognized by the system. The occurrence of an error causes suspension of the normal program execution and the control is passed to an error handler. The concept of error handlers makes it possible to respond to and, possibly, recover from errors that arise during program execution. If further execution is not possible, the error handler can at least assure that the program is given a graceful abortion.

Programming principles

When an error occurs, the error handler of the routine is called (if there is one). It is also possible to create an error from within the program and then jump to the error handler.

In an error handler, errors can be handled using ordinary instructions. The system data ERRNO can be used to determine the type of error that has occurred. A return from the error handler can then take place in various ways (RETURN, RETRY, TRYNEXT, and RAISE).

If the current routine does not have an error handler, the internal error handler of the robot takes over directly. The internal error handler gives an error message and stops program execution with the program pointer at the faulty instruction.

Creating an error situation from within the program Instruction

<table>

<td>Text in an error message</td>
</tr>
</tbody>
</table>

### Configuration for error handling

<table>
<thead>
<tr>
<th>System parameter</th>
<th>Used to define</th>
</tr>
</thead>
<tbody>
<tr>
<td>No Of Retry</td>
<td>The number of times a failing instruction will be retried if the error handler use RETRY. No Of Retry belongs to the type System Misc in the topic Controller.</td>
</tr>
</tbody>
</table>

### Error handlers

Any routine may include an error handler. The error handler is really a part of the routine, and the scope of any routine data also comprises the error handler of the routine. If an error occurs during the execution of the routine, control is transferred to its error handler.
1 Basic RAPID programming

1.12 Error recovery

Continued

Example:

```plaintext
FUNC num safediv( num x, num y)
    RETURN x / y;
ERROR
    IF ERRNO = ERR_DIVZERO THEN
        TPWrite "The number cannot be equal to 0";
        RETURN x;
    ENDIF
ENDFUNC
```

The system variable `ERRNO` contains the error number of the (most recent) error and can be used by the error handler to identify that error. After any necessary actions have been taken, the error handler can:

- Resume execution, starting with the instruction in which the error occurred. This is done using the `RETRY` instruction. If this instruction causes the same error again, up to four error recoveries will take place; after that execution will stop. To be able to make more than four retries, you have to configure the system parameter `No Of Retry`, see Technical reference manual - System parameters.
- Resume execution, starting with the instruction following the instruction in which the error occurred. This is done using the `TRYNEXT` instruction.
- Return control to the caller of the routine using the `RETURN` instruction. If the routine is a function, the `RETURN` instruction must specify an appropriate return value.
- Propagate the error to the caller of the routine using the `RAISE` instruction.

System error handler

When an error occurs in a routine that does not contain an error handler or when the end of the error handler is reached (ENDFUNC, ENDPCH or ENDTAP), the system error handler is called. The system error handler just reports the error and stops the execution.

In a chain of routine calls, each routine may have its own error handler. If an error occurs in a routine with an error handler, and the error is explicitly propagated using the RAISE instruction, the same error is raised again at the point of the call of the routine - the error is propagated. When the top of the call chain (the entry routine of the task) is reached without any error handler being found or when the end of any error handler is reached within the call chain, the system error handler is called. The system error handler just reports the error and stops the execution. Since a trap routine can only be called by the system (as a response to an interrupt), any propagation of an error from a trap routine is made to the system error handler. Error recovery is not available for instructions in the backward handler. Such errors are always propagated to the system error handler.

It is not possible to recover from or respond to errors that occur within an error handler. Such errors are always propagated to the system error handler.

Continues on next page
Errors raised by the program

In addition to errors detected and raised by the robot, a program can explicitly raise errors using the RAISE instruction. This facility can be used to recover from complex situations. It can, for example, be used to escape from deeply nested code positions. Error numbers 1-90 may be used in the raise instruction. Explicitly raised errors are treated exactly like errors raised by the system.

The event log

Errors that are handled by an error handler still result in a warning in the event log. By looking in the event log it is possible to track what errors that have occurred. If you want an error to be handled without writing a warning in the event log, use the instruction SkipWarn in the error handler. This can be useful when using the error handler to test something (for example if a file exists) without leaving any trails if the test fails.
1 Basic RAPID programming

1.13 UNDO

Introduction

RAPID routines may contain an UNDO handler. The handler is executed automatically if the program pointer is moved out of the routine. This is supposed to be used for cleaning up remaining side-effects after partially executed routines, for example canceling modal instructions (such as opening a file). Most parts of the RAPID language can be used in an UNDO handler, but there are some limitations, for example motion instructions.

Terminology

The following terms are related to UNDO.

- UNDO: The execution of cleaning up code prior to a program reset.
- UNDO handler: An optional part of a RAPID procedure or function containing RAPID code that is executed on an UNDO.
- UNDO routine: A procedure or a function with an UNDO handler.
- Call-chain: All procedures or functions currently associated to each other through not-yet finished routine invocations. Assumed to start in the routine Main if nothing else is specified.
- UNDO context: When the current routine is part of a call-chain starting in an UNDO handler.

When to use UNDO

A RAPID routine can be aborted at any point by moving the program pointer out of the routine. In some cases, when the program is executing certain sensitive routines, it is unsuitable to abort. Using UNDO it is possible to protect such sensitive routines against an unexpected program reset. With UNDO it is possible to have certain code executed automatically if the routine is aborted. This code should typically perform clean-up actions, for instance closing a file.

UNDO behavior in detail

When UNDO is activated, all UNDO-handlers in the current call-chain are executed. These handlers are optional parts of a RAPID procedure or function, containing RAPID code. The currently active UNDO-handlers are those who belong to procedures or functions that has been invoked but not yet terminated, that is the routines in the current call-chain.

UNDO is activated when the program pointer is unexpectedly moved out of an UNDO-routine, for instance if the user moves the program pointer to Main. UNDO is also started if an EXIT instruction is executed, causing the program to be reset, or if the program is reset for some other reason, for instance when changing some configuration or if the program or module is deleted. However, UNDO is not started if the program reaches the end of the routine or a RETURN statement and returns as usual from the routine.

If there is more than one UNDO routine in the call-chain, the UNDO-handlers of the routines will be processed in the same order the routines would have returned.
bottom-up. The UNDO-handler closest to the end of the call-chain will execute first and the one closest to Main will execute last.

Limitations

An UNDO-handler can access any variable or symbol reachable from the normal routine body, including locally declared variables. RAPID code that are to be executed in UNDO context has however limitations.

An UNDO-handler must not contain STOP, DEBUGBREAK, RAISE, or RETURN. If an attempt is made to use any of these instructions in UNDO context, the instruction will be ignored and an ELOG warning is generated.

Motion instructions, for example MoveL, are not allowed in UNDO context either. The execution is always continuous in UNDO, it is not possible to step. When UNDO starts, the execution mode is set to continuous automatically. After the UNDO session is finished, the old execution mode is restored.

If the program is stopped while executing an UNDO-handler, the rest of the handler will not be executed. If there are additional UNDO-handlers in the call-chain that have not yet been executed, they will be ignored as well. This will result in an ELOG warning. This also includes stopping due to a runtime error.

The program pointer is not visible in an UNDO-handler. When UNDO executes, the program pointer remains at its old location, but is updated when the UNDO-handler(s) are finished.

An EXIT instruction aborts UNDO in similar way as a Run-time error or a Stop. The rest of the UNDO-handlers are ignored and the program pointer is moved to Main.

Example

The program:

PROC B
    TPWrite "In Routine B";
    Exit;
    UNDO
    TPWrite "In UNDO of routine B";
ENDPROC

PROC A
    TPWrite "In Routine A";
    B;
ENDPROC

PROC main
    TPWrite "In main";
    A;
    UNDO
    TPWrite "In UNDO of main";
ENDPROC

The output:

In main
In Routine A

1.14 System & time

Description
System and time instructions allow the user to measure, inspect and record time.

Programming principles
Clock instructions allow the user to use clocks that function as stopwatches. In this way the robot program can be used to time any desired event.
The current time or date can be retrieved in a string. This string can then be displayed to the operator on the FlexPendant display or used to time and date-stamp log files.
It is also possible to retrieve components of the current system time as a numeric value. This allows the robot program to perform an action at a certain time or on a certain day of the week.

1.15 Mathematics

1.15 Mathematics

Description
Mathematical instructions and functions are used to calculate and change the value of data.

Programming principles
Calculations are normally performed using the assignment instruction, for example
reg1:= reg2 + reg3 / 5. There are also some instructions used for simple calculations, such as to clear a numeric variable.

### 1 Basic RAPID programming

#### 1.15 Mathematics

**Function** | **Used to** |
---|---|
ASin | Calculate the arc sine value |
ASinDnum | Calculate the arc sine value |
ATan | Calculate the arc tangent value in the range [-90,90] |
ATanDnum | Calculate the arc tangent value in the range [-90,90] |
ATan2 | Calculate the arc tangent value in the range [-180,180] |
ATan2Dnum | Calculate the arc tangent value in the range [-180,180] |
Cos | Calculate the cosine value |
CosDnum | Calculate the cosine value |
Sin | Calculate the sine value |
SinDnum | Calculate the sine value |
Tan | Calculate the tangent value |
TanDnum | Calculate the tangent value |
EulerZYX | Calculate Euler angles from an orientation |
OrientZYX | Calculate the orientation from Euler angles |
PoseInv | Invert a pose |
PoseMult | Multiply a pose |
PoseVect | Multiply a pose and a vector |
VectMagn | Calculate the magnitude of a pos vector |
DotProd | Calculate the dot (or scalar) product of two pos vectors |
CrossProd | Calculate the cross (or vector) product of two pos vectors |
NOrient | Normalize unnormalized orientation (quaternion) |

**String digit functions**

**Function** | **Used to** |
---|---|
StrDigCmp | Numeric compare of two strings with only digits |
StrDigCalc | Arithmetic operations on two strings with only digits |

**Data type** | **Used to** |
---|---|
stringdig | String with only digits |

**Bit functions**

**Instruction** | **Used to** |
---|---|
BitClear | Clear a specified bit in a defined byte or dnum data. |
BitSet | Set a specified bit to 1 in a defined byte or dnum data. |

**Function** | **Used to** |
---|---|
BitCheck | Check if a specified bit in a defined byte data is set to 1. |
BitCheckDnum | Check if a specified bit in a defined dnum data is set to 1. |
BitAnd | Execute a logical bitwise AND operation on data types byte. |

1.17 RAPID support instructions

Description
Various functions for supporting of the RAPID language:
- Get system data
- Read configuration data
- Write configuration data
- Restart the controller
- Test system data
- Get object name
- Get task name
- Search for symbols
- Get current event type, execution handler or execution level
- Read service information

Get system data
Instruction to fetch the value and (optional) the symbol name for the current system data of specified type.

<table>
<thead>
<tr>
<th>Instruction</th>
<th>Used to</th>
</tr>
</thead>
<tbody>
<tr>
<td>GetSysData</td>
<td>Get data and name of current active tool or work object.</td>
</tr>
<tr>
<td>ResetPPMoved</td>
<td>Reset state for the program pointer moved in manual mode.</td>
</tr>
<tr>
<td>SetSysData</td>
<td>Activate a specified system data name for a specified data type.</td>
</tr>
</tbody>
</table>

Function | Used to                                                                 |
-----------|-------------------------------------------------------------------------|
IsSysID    | Test the system identity.                                               |
IsStopStateEvent | Get information about the movement of the program pointer (PP).               |
PPMovedInManMode | Test whether the program pointer is moved in manual mode.               |
RobOS     | Check if the execution is performed on robot controller (RC) or virtual controller (VC). |

Get information about the system
Function to get information about serial number, software version, robot type, LAN IP address or controller language.

<table>
<thead>
<tr>
<th>Function</th>

<tr>
<td>HexToDec</td>
<td>Convert a number specified in a readable string in the base 16 to the base 10</td>
</tr>
</tbody>
</table>
1 Basic RAPID programming

1.20 Multitasking

Description

The events in a robot cell are often in parallel, so why are the programs not in parallel?

Multitasking RAPID is a way to execute programs in (pseudo) parallel. One parallel program can be placed in the background or foreground of another program. It can also be on the same level as another program.

For all settings, see Technical reference manual - System parameters.

Limitations

There are a few restrictions on the use of Multitasking RAPID.

- Do not mix up parallel programs with a PLC. The response time is the same as the interrupt response time for one task. This is true, of course, when the task is not in the background of another busy program.
- When running a Wait instruction in manual mode, a simulation box will come up after 3 seconds. This will only occur in a NORMAL task.
- Move instructions can only be executed in the motion task (the task bind to program instance 0, see Technical reference manual - System parameters).
- The execution of a task will halt during the time that some other tasks are accessing the file system, that is if the operator chooses to save or open a program, or if the program in a task uses the load/erase/read/write instructions.
- The FlexPendant cannot access other tasks than a NORMAL task. So, the development of RAPID programs for other SEMISTATIC or STATIC tasks can only be done if the code is loaded into a NORMAL task, or offline.

Basics

To use this function the robot must be configured with one extra TASK for each additional program. Each task can be of type NORMAL, STATIC, or SEMISTATIC.

Up to 20 different tasks can be run in pseudo parallel. Each task consists of a set of modules, in the same way as the normal program. All the modules are local in each task.

Variables, constants, and persistents are local in each task, but global persistents are not. A persistent is global by default, if not declared as LOCAL or TASK. A global persistent with the same name and type is reachable in all tasks that it is declared in. If two global persistents have the same name, but their type or size (array dimension) differ, a runtime error will occur.

A task has its own trap handling and the event routines are triggered only on its own task system states (for example Start/Stop/Restart...).
General instructions and functions

<table>
<thead>
<tr>

</tbody>
</table>

<table>
<thead>
<tr>
<th>Data type</th>
<th>Used to</th>
</tr>
</thead>
<tbody>
<tr>
<td>taskid</td>
<td>Identify available program tasks in the system.</td>
</tr>
<tr>
<td>syncident</td>
<td>Specify the name of a synchronization point</td>
</tr>
<tr>
<td>tasks</td>
<td>Specify several RAPID program tasks</td>
</tr>
</tbody>
</table>

Synchronizing the tasks

In many applications a parallel task only supervises some cell unit, quite independently of the other tasks being executed. In such cases, no synchronization mechanism is necessary. But there are other applications which need to know what the main task is doing, for example.

Synchronizing using polling

This is the easiest way to do it, but the performance will be the slowest. Persistents are used together with the instructions `WaitUntil`, `IF`, `WHILE`, or `GOTO`.

If the instruction `WaitUntil` is used, it will poll internally every 100 ms. Do not poll more frequently in other implementations.

Example

```plaintext
TASK 1:
MODULE module1
PERS bool startsync:=FALSE;
PROC main()
    startsync:= TRUE;
ENDPROC
ENDMODULE

TASK 2:
MODULE module2
PERS bool startsync:=FALSE;
PROC main()
    WaitUntil startsync;
ENDPROC
ENDMODULE
```

Continues on next page
Synchronizing using an interrupt

The instructions SetDO and ISignalDO are used.

Example

```rapid
TASK 1:
MODULE module1
PROC main()
    SetDO do1, 1;
ENDPROC
ENDMODULE

TASK 2:
MODULE module2
VAR intnum isiint1;
PROC main()
    CONNECT isiint1 WITH isi_trap;
    ISignalDO do1, 1, isiint1;
    WHILE TRUE DO
        WaitTime 200;
    ENDWHILE
    IDelete isiint1;
ENDPROC
TRAP isi_trap
ENDTRAP
ENDMODULE
```

Intertask communication

All types of data can be sent between two (or more) tasks with global persistent variables.

A global persistent variable is global in all tasks. The persistent variable must be of the same type and size (array dimension) in all tasks that declared it. Otherwise a runtime error will occur.

Example

```rapid
TASK 1:
MODULE module1
PERS bool startsync:=FALSE;
PERS string stringtosend:="";
PROC main()
    stringtosend:="this is a test";
    startsync:= TRUE
ENDPROC
ENDMODULE
```

Continues on next page
TASK 2:

```rapid
MODULE module2
PERS bool startsync:=FALSE;
PERS string stringtosend:="";
PROC main()

  WaitUntil startsync;
  !read string
  IF stringtosend = "this is a test" THEN
    ...
  ENDIF
ENDPROC
ENDMODULE
```

**Type of task**

Each task can be of type **NORMAL**, **STATIC** or **SEMISTATIC**.

- **STATIC** and **SEMISTATIC** tasks are started in the system startup sequence. If the task is of type **STATIC**, it will be restarted at the current position (where PP was when the system was powered off). If the type is set to **SEMISTATIC**, it will be started from the beginning each time the power is turned on, and modules specified in the system parameters will be reloaded if the module file is newer than the loaded module.
- Tasks of type **NORMAL** will not be started at startup. They are started in the normal way, for example, from the FlexPendant.

**Priorities**

The way to run the tasks as default is to run all tasks at the same level in a round robbin way (one basic step on each instance). But it is possible to change the priority of one task by putting the task in the background of another. Then the background will only execute when the foreground is waiting for some events, or has stopped the execution (idle). A robot program with move instructions will be in an idle state most of the time.

The example below describes some situations where the system has 10 tasks (see Figure 9).

- Round robbin chain 1: tasks 1, 2, and 9 are busy.
- Round robbin chain 2: tasks 1, 4, 5, 6 and 9 are busy tasks 2 and 3 are idle.
- Round robbin chain 3: tasks 3, 5 and 6 are busy tasks 1, 2, 9 and 10 are idle.
Round robin chain 4: tasks 7 and 8 are busy tasks 1, 2, 3, 4, 5, 6, 9 and 10 are idle.

![Diagram of round robin chain 4 tasks](image)

**Figure 9: The tasks can have different priorities**

**TrustLevel**

TrustLevel handles the system behavior when a SEMISTATIC or STATIC task is stopped for some reason or not executable.

- **SysFail** - This is the default behavior, all other NORMAL tasks will also stop, and the system is set to state SYS_FAIL. All jog and program start orders will be rejected. Only a new warm start reset the system. This should be used when the task has some security supervisions.
- **SysHalt** - All NORMAL tasks will be stopped. The system is forced to motors off. When taking up the system to motors on it is possible to jog the robot, but a new attempt to start the program will be rejected. A new warm start will reset the system.
- **SysStop** - All NORMAL tasks will be stopped, but can be restarted. Jogging is also possible.
- **NoSafety** - Only the actual task itself will stop.

See Technical reference manual - System parameters, topic Controller, type Task.

**Recommendation**

When specifying task priorities, think about the following:

- Always use the interrupt mechanism or loops with delays in supervision tasks. Otherwise the FlexPendant will never get any time to interact with the
user. And if the supervision task is in foreground, it will never allow another task in background to execute.
1.21 Backward execution

Description

A program can be executed backwards one instruction at a time. The following general restrictions are valid for backward execution:

- It is not possible to step backwards out of a **IF**, **FOR**, **WHILE** and **TEST** statement.
- It is not possible to step backwards out of a routine when reaching the beginning of the routine.
- Motion settings instructions, and some other instructions affecting the motion, cannot be executed backwards. If attempting to execute such an instruction a warning will be written in the event log.
- When executing backward handlers and there is an execution error, it will not be possible to handle the error in an error handler.

Backward handlers

Procedures may contain a backward handler that defines the backward execution of a procedure call. If calling a routine inside the backward handler, the routine is executed forward.

The backward handler is really a part of the procedure and the scope of any routine data also comprises the backward handler of the procedure.

Instructions in the backward or error handler of a routine may not be executed backwards. Backward execution cannot be nested, that is two instructions in a call chain may not simultaneously be executed backwards.

A procedure with no backward handler cannot be executed backwards. A procedure with an empty backward handler is executed as “no operation”.

Example 1

```rapid
PROC MoveTo ()
  MoveL p1,v500,z10,tool1;
  MoveC p2,p3,v500,z10,tool1;
  MoveL p4,v500,z10,tool1;
BACKWARD
  MoveL p4,v500,z10,tool1;
  MoveC p2,p3,v500,z10,tool1;
  MoveL p1,v500,z10,tool1;
ENDPROC
```

When the procedure is called during forward execution, the following occurs:

- MoveL p1,v500,z10,tool1;
- MoveC p2,p3,v500,z10,tool1;
- MoveL p4,v500,z10,tool1;

Example 2

```rapid
PROC MoveTo ()
  MoveL p1,v500,z10,tool1;
  MoveC p2,p3,v500,z10,tool1;
  MoveL p4,v500,z10,tool1;
```

Continues on next page
BACKWARD
  MoveL p4,v500,z10,tool1;
  MoveC p2,p3,v500,z10,tool1;
  MoveL p1,v500,z10,tool1;
ENDPROC

When the procedure is called during forward execution, the following code is executed (the code of the procedure until the backward handler):
  MoveL p1,v500,z10,tool1;
  MoveC p2,p3,v500,z10,tool1;
  MoveL p4,v500,z10,tool1;

When the procedure is called during backwards execution, the following code is executed (the code in the backward handler):
  MoveL p4,v500,z10,tool1;
  MoveC p2,p3,v500,z10,tool1;
  MoveL p1,v500,z10,tool1;

Limitation of move instructions in the backward handler

The move instruction type and sequence in the backward handler must be a mirror of the move instruction type and sequence for forward execution in the same routine:

PROC MoveTo ()
  MoveL p1,v500,z10,tool1;
  MoveC p2,p3,v500,z10,tool1;
  MoveL p4,v500,z10,tool1;
  BACKWARD
  MoveL p4,v500,z10,tool1;
  MoveC p2,p3,v500,z10,tool1;
  MoveL p1,v500,z10,tool1;
ENDPROC

Note that the order of CirPoint p2 and ToPoint p3 in the MoveC should be the same.

Move instructions includes all instructions that result in some movement of the robot or additional axes, such as MoveL, SearchC, TriggJ, ArcC, or PaintL.

WARNING

Any departures from this programming limitation in the backward handler can result in faulty backward movement. Linear movement can result in circular movement and vice versa, for some part of the backward path.

Behavior of the backward execution

MoveC and nostepin routines

When stepping forward through a MoveC instruction, the robot stops at the circular point (the instruction is executed in two steps). However, when stepping backwards though a MoveC instruction, the robot does not stop at the circular point (the instruction is executed in one step).
1 Basic RAPID programming

1.21 Backward execution

Continued

It is not allowed to change from forward to backward execution when the robot is executing a MoveC instruction.

To be able to change from forward to backward execution in a nostepin routine, or vice versa, the system parameter StepOutNoStepin must be set.

Target, movement type and speed

When stepping forward though the program code, a program pointer indicates the next instruction to execute and a motion pointer indicates the move instruction that the robot is performing.

When stepping backward though the program code, the program pointer indicates the instruction above the motion pointer. When the program pointer indicates one move instruction and the motion pointer indicates another, the next backward movement will move to the target indicated by the program pointer, using the movement type and speed indicated by the motion pointer.

An exception, in terms of backward execution speed, is the instruction MoveExtJ. This instruction use the speed related to the robtarget for both forward and backward execution.

Example

This example illustrates the behavior when stepping backwards through move instructions. The program pointer and motion pointer helps you keep track of where the RAPID execution is and where the robot is.

Continues on next page
1 The program is stepped forward until the robot is in p5. The motion pointer will indicate p5 and the program pointer will indicate the next move instruction (MoveL p6).

2 The first press of the backward button will not move the robot, but the program pointer will move to the previous instruction (MoveC p3, p4). This indicates that this is the instruction that will be executed the next time backward button is pressed.

3 The second press of the backward button will move the robot to p4 linearly with the speed v300. The target for this movement (p4) is taken from the MoveC instruction. The type of movement (linear) and the speed are taken from the instruction below (MoveL p5). The motion pointer will indicate p4 and the program pointer will move up to MoveL p2.

4 The third press of the backward button will move the robot circularly, via p3, to p2 with the speed v100. The target p2 is taken from the instruction MoveL p2. The type of movement (circular), the circular point (p3) and the speed are taken from the MoveC instruction. The motion pointer will indicate p2 and the program pointer will move up to MoveL p1.

5 The fourth press of the backward button will move the robot linearly to p1 with the speed v200. The motion pointer will indicate p1 and the program pointer will move up to MoveJ p0.

6 The first press of the forward button will not move the robot, but the program pointer will move to the next instruction (MoveL p2).

7 The second press of the forward button will move the robot to p2 with the speed v200.
2 Motion and I/O programming

2.1 Coordinate systems

2.1.1 The tool center point of the robot (TCP)

Description

The position of the robot and its movements are always related to the tool center point (TCP). This point is normally defined as being somewhere on the tool, for example in the muzzle of a glue gun, at the center of a gripper or at the end of a grading tool.

Several TCPs (tools) may be defined, but only one may be active at any one time. When a position is recorded, it is the position of the TCP that is recorded. This is also the point that moves along a given path, at a given velocity.

If the robot is holding a work object and working on a stationary tool, a stationary TCP is used. If that tool is active, the programmed path and speed are related to the work object. See Stationary TCPs on page 113.

2.1.2 Coordinate systems used to determine the position of the TCP

Description

The tool (TCP) position can be specified in different coordinate systems to facilitate programming and adjustment of programs.

The coordinate system defined depends on what the robot has to do. When no coordinate system is defined, the robot’s positions are defined in the base coordinate system.

Base coordinate system

In a simple application, programming can be done in the base coordinate system; here the z-axis is coincident with axis 1 of the robot.

The base coordinate system is located on the base of the robot:

- The origin is situated at the intersection of axis 1 and the base mounting surface.
- The xy plane is the same as the base mounting surface.
- The x-axis points forwards.
- The y-axis points to the left (from the perspective of the robot).
- The z-axis points upwards.

World coordinate system

If the robot is floor mounted, programming in the base coordinate system is easy. If, however, the robot is mounted upside down (suspended), programming in the base coordinate system is more difficult because the directions of the axes are not the same as the principal directions in the working space. In such cases, it is useful to define a world coordinate system. The world coordinate system will be coincident with the base coordinate system, if it is not specifically defined.

Sometimes, several robots work within the same working space. A common world coordinate system is used in this case to enable the robot programs to communicate with one another. It can also be a good idea to use this when the positions are related to a fixed point in the workshop.

Continues on next page
The following figure shows two robots (one suspended) with a common world coordinate system.

User coordinate system

A robot can work with different fixtures or working surfaces having different positions and orientations. A user coordinate system can be defined for each fixture. If all positions are stored in object coordinates, you will not need to reprogram if a fixture must be moved or turned. By moving(turning the user coordinate system as much as the fixture has been moved/turned, all programmed positions will follow the fixture and no reprogramming will be required.

The user coordinate system is defined based on the world coordinate system.
The following figure shows two user coordinate systems that describe the position of two different fixtures.

Object coordinate system

The user coordinate system is used to get different coordinate systems for different fixtures or working surfaces. A fixture, however, may include several work objects that are to be processed or handled by the robot. Thus, it often helps to define a coordinate system for each object in order to make it easier to adjust the program if the object is moved or if a new object, the same as the previous one, is to be programmed at a different location. A coordinate system referenced to an object is called an object coordinate system. This coordinate system is also very suited to off-line programming since the positions specified can usually be taken directly from a drawing of the work object. The object coordinate system can also be used when jogging the robot.

The object coordinate system is defined based on the user coordinate system.
The following figure shows two object coordinate systems that describe the position of two different work objects located in the same fixture.

The programmed positions are always defined relative to an object coordinate system. If a fixture is moved/turned, this can be compensated for by moving/turning the user coordinate system. Neither the programmed positions nor the defined object coordinate systems need to be changed. If the work object is moved/turned, this can be compensated for by moving/turning the object coordinate system.

If the user coordinate system is movable, that is, coordinated additional axes are used, then the object coordinate system moves with the user coordinate system. This makes it possible to move the robot in relation to the object even when the workbench is being manipulated.
Displacement coordinate system

Sometimes, the same path is to be performed at several places on the same object. To avoid having to re-program all positions each time, a coordinate system, known as the displacement coordinate system, is defined. This coordinate system can also be used in conjunction with searches, to compensate for differences in the positions of the individual parts.

The displacement coordinate system is defined based on the object coordinate system.

If program displacement is active, all positions are displaced.
Coordinated additional axes

Coordination of user coordinate system

If a work object is placed on an external mechanical unit, that is moved whilst the robot is executing a path defined in the object coordinate system, a movable user coordinate system can be defined. The position and orientation of the user coordinate system will, in this case, be dependent on the axes rotations of the external unit. The programmed path and speed will thus be related to the work object and there is no need to consider the fact that the object is moved by the external unit.

The following figure shows a user coordinate system, defined to follow the movements of a 3-axis external mechanical unit.
Coordination of base coordinate system

A movable coordinate system can also be defined for the base of the robot. This is of interest for the installation when the robot is mounted on a track or a gantry, for example. The position and orientation of the base coordinate system will, as for the moveable user coordinate system, be dependent on the movements of the external unit. The programmed path and speed will be related to the object coordinate system and there is no need to think about the fact that the robot base is moved by an external unit. A coordinated user coordinate system and a coordinated base coordinate system can both be defined at the same time.

The following figure shows coordinated interpolation with a track moving the base coordinate system of the robot.

![Diagram of coordinated interpolation with a track moving the base coordinate system of the robot.](image)

To be able to calculate the user and the base coordinate systems when involved units are moved, the robot must be aware of:

- The calibration positions of the user and the base coordinate systems.
- The relations between the angles of the additional axes and the translation/rotation of the user and the base coordinate systems.
- These relations are defined in the system parameters.
2.1.3 Coordinate systems used to determine the direction of the tool

Description
The orientation of a tool at a programmed position is given by the orientation of the tool coordinate system. The tool coordinate system is referenced to the wrist coordinate system, defined at the mounting flange on the wrist of the robot.

Wrist coordinate system
In a simple application, the wrist coordinate system can be used to define the orientation of the tool; here the z-axis is coincident with axis 6 of the robot.

The wrist coordinate system cannot be changed and is always the same as the mounting flange of the robot in the following respects:
- The origin is situated at the center of the mounting flange (on the mounting surface).
- The x-axis points in the opposite direction, towards the control hole of the mounting flange.
- The z-axis points outwards, at right angles to the mounting flange.

Tool coordinate system
The tool mounted on the mounting flange of the robot often requires its own coordinate system to enable definition of its TCP, which is the origin of the tool coordinate system. The tool coordinate system can also be used to get appropriate motion directions when jogging the robot.

If a tool is damaged or replaced, all you have to do is redefine the tool coordinate system. The program does not normally have to be changed.

The TCP (origin) is selected as the point on the tool that must be correctly positioned, for example the muzzle on a glue gun. The tool coordinate axes are defined as those natural for the tool in question.

Continues on next page
The following figure shows a tool coordinate system, as usually defined for an arc-welding gun (left) and a spot welding gun (right).

The tool coordinate system is defined based on the wrist coordinate system. The following figure shows the tool coordinate system defined relative to the wrist coordinate system, here for a gripper.
Stationary TCPs

If the robot is holding a work object and working on a stationary tool, a stationary TCP is used. If that tool is active, the programmed path and speed are related to the work object held by the robot. This means that the coordinate systems will be reversed, as in the following figure.

The following figure shows a stationary TCP, where the object coordinate system is based on the wrist coordinate system.

![Stationary TCP Diagram]

In the following figure, neither the user coordinate system nor program displacement is used. It is, however, possible to use them and, if they are used, they will be related to each other.

![Additional Diagram]

Program displacement can also be used together with stationary TCPs.
2 Motion and I/O programming

2.2 Positioning during program execution

2.2.1 Introduction

How movements are performed

During program execution, positioning instructions in the robot program control all movements. The main task of the positioning instructions is to provide the following information on how to perform movements:

- The destination point of the movement (defined as the position of the tool center point, the orientation of the tool, the configuration of the robot and the position of the additional axes).
- The interpolation method used to reach the destination point, for example joint interpolation, linear interpolation or circle interpolation.
- The velocity of the robot and additional axes.
- The zone data (defines how the robot and the additional axes are to pass the destination point, for example stop point or fly-by point).
- The coordinate systems (tool, user and object) used for the movement.

As an alternative to defining the velocity of the robot and the additional axes, the time for the movement can be programmed. This should, however, be avoided if the weaving function is used. Instead the velocities of the orientation and additional axes should be used to limit the speed, when small or no TCP-movements are made.

**WARNING**

In material handling and pallet applications with intensive and frequent movements, the drive system supervision may trip out and stop the robot in order to prevent overheating of drives or motors. If this occurs, the cycle time needs to be slightly increased by reducing programmed speed or acceleration.

2.2.2 Interpolation of the position and orientation of the tool

Joint interpolation

When path accuracy is not too important, this type of motion is used to move the tool quickly from one position to another. Joint interpolation also allows an axis to move from any location to another within its working space, in a single movement. All axes move from the start point to the destination point at constant axis velocity, see the following figure.

Joint interpolation is often the fastest way to move between two points as the robot axes follow the closest path between the start point and the destination point (from the perspective of the axis angles).

The velocity of the tool center point is expressed in mm/s (in the object coordinate system). As interpolation takes place axis-by-axis, the velocity will not be exactly the programmed value.

During interpolation, the velocity of the limiting axis, that is the axis that travels fastest relative to its maximum velocity in order to carry out the movement, is determined. Then, the velocities of the remaining axes are calculated so that all axes reach the destination point at the same time.

All axes are coordinated in order to obtain a path that is independent of the velocity. Acceleration is automatically optimized to the max performance of the robot.

Linear interpolation

During linear interpolation, the TCP travels along a straight line between the start and destination points.

To obtain a linear path in the object coordinate system, the robot axes must follow a non-linear path in the axis space. The more non-linear the configuration of the robot is, the more accelerations and decelerations are required to make the tool move in a straight line and to obtain the desired tool orientation. If the configuration is extremely non-linear (for example in the proximity of wrist and arm singularities), one or more of the axes will require more torque than the motors can give. In this case, the velocity of all axes will automatically be reduced.
The orientation of the tool remains constant during the entire movement unless a reorientation has been programmed. If the tool is reorientated, it is rotated at constant velocity.

A maximum rotational velocity (in degrees per second) can be specified when rotating the tool. If this is set to a low value, reorientation will be smooth, irrespective of the velocity defined for the tool center point. If it is a high value, the reorientation velocity is only limited by the maximum motor speeds. As long as no motor exceeds the limit for the torque, the defined velocity will be maintained. If, on the other hand, one of the motors exceeds the current limit, the velocity of the entire movement (with respect to both the position and the orientation) will be reduced.

All axes are coordinated in order to obtain a path that is independent of the velocity. Acceleration is optimized automatically.

Circular interpolation

A circular path is defined using three programmed positions that define a circle segment. The first point to be programmed is the start of the circle segment. The next point is a support point (circle point) used to define the curvature of the circle, and the third point denotes the end of the circle. The three programmed points should be dispersed at regular intervals along the arc of the circle to make this as accurate as possible.

The orientation defined for the support point is used to select between the short and the long twist for the orientation from start to destination point. If the programmed orientation is the same relative to the circle at the start and the destination points, and the orientation at the support is close to the same orientation relative to the circle, the orientation of the tool will remain constant relative to the path.

The following figure shows circular interpolation with a short twist for part of a circle (circle segment) with a start point, circle point and destination point.
However, if the orientation at the support point is programmed closer to the orientation rotated 180°, the alternative twist is selected, as shown in the following figure.

As long as all motor torques do not exceed the maximum permitted values, the tool will move at the programmed velocity along the arc of the circle. If the torque of any of the motors is insufficient, the velocity will automatically be reduced at those parts of the circular path where the motor performance is insufficient.

All axes are coordinated in order to obtain a path that is independent of the velocity. Acceleration is optimized automatically.

During execution in the proximity of a singular point, linear or circular interpolation may be problematic. In this case, it is best to use modified interpolation, which means that the wrist axes are interpolated axis-by-axis, with the TCP following a linear or circular path. The orientation of the tool, however, will differ somewhat from the programmed orientation. The resulting orientation in the programmed point may also differ from the programmed orientation due to two singularities.
The first singularity is when TCP is straight ahead from axis 2 (a2 in the figure above). The TCP cannot pass to the other side of axis 2, instead will axis 2 and 3 fold a bit more to keep the TCP on the same side and the end orientation of the move will then be turned away from the programmed orientation with the same size.

The second singularity is when TCP will pass near the z-axis of axis 1 (z1 in the figure above). The axis 1 will in this case turn around with full speed and the tool reorientation will follow in the same way. The direction of the turn is dependent of what side the TCP will go. We recommend to change to joint interpolation (MoveJ) near the z-axis. Note that it is the TCP that makes the singularity, not the WCP as when SingArea\Off is used.

In the SingArea\Wrist case the orientation in the circle support point will be the same as programmed. However, the tool will not have a constant direction relative to the circle plane as for normal circular interpolation. If the circle path passes a singularity, the orientation in the programmed positions sometimes must be modified to avoid big wrist movements, which can occur if a complete wrist re-configuration is generated when the circle is executed (joints 4 and 6 moved 180 degrees each).
2.2.3 Interpolation of corner paths

Description
Corner paths are used to get continuous movements past programmed positions. In this way, positions can be passed at high speed without having to reduce the speed unnecessarily. A fly-by point generates a corner path (parabola path) past the programmed position. The beginning and end of this corner path are defined by a zone around the programmed position.

Corner zone
for the TCP path

Corner path

Programmed position

Corner zone 
for the TCP path

Corner path

Programmed position

All axes are coordinated in order to obtain a path that is independent of the velocity. Speed and acceleration are optimized automatically.

Defining a corner path
The size of the corner zone is defined in the data type \texttt{zonedata}, which is used as an argument in move instructions. For more information, see \texttt{zonedata} in \textit{Technical reference manual - RAPID Instructions, Functions and Data types}.

Smooth transitions between different speeds
If different TCP speeds have been programmed before and after the corner position, the transition will be smooth and take place within the corner path without affecting the actual path.

If different reorientation velocities are programmed before and after the corner position, and if the reorientation velocities limit the movement, the transition from one velocity to the other will take place smoothly within the corner path.

Fine-tuning the path
If the tool is to carry out a process (such as arc-welding, gluing or water cutting) along the corner path, the size of the zone can be adjusted to get the desired path. If the shape of the parabolic corner path does not match the object geometry, the programmed positions can be placed closer together, making it possible to approximate the desired path using two or more smaller parabolic paths.
**Corner paths with reorientation**

A fly-by point can have one zone size for TCP position (position zone) and one zone size for tool reorientation and movement of additional axes (reorientation and additional axis zone).

The reorientation and additional axis zone can be defined similar to the position zone. The reorientation and additional axis zone is usually set larger than the position zone. In this case, the reorientation will start interpolating towards the orientation of the next position before the corner path starts. The reorientation will then be smoother.

The tool will be reorientated so that the orientation at the end of the zone will be the same as if a stop point had been programmed, see the following figures. Note that the orientation outside the reorientation and additional axis zone is the same for both cases (position C - E) but the orientation inside the zone changes more smoothly than the programmed positions.

![Position zone and Reorientation and additional axis zone](image)

If the middle position is a fly-by point, program execution will look like this.

![Position zone and Reorientation and additional axis zone](image)

If three positions with different tool orientations are programmed as stop points, program execution will look like this.

The reorientation and additional axis zone is normally expressed in mm. In this way, you can determine directly where on the path the zone begins and ends. If the tool is not moved, the size of the zone is expressed in angle of rotation degrees instead of TCP-mm.

The reorientation and additional axis zone is also used for additional axes, in the same manner as for orientation. If the reorientation and additional axis zone is set to be larger than the position zone, the interpolation of the additional axes towards the destination of the next programmed position, will be started before the TCP position corner path starts. This can be used for smoothing additional axes movements in the same way as the tool orientation is used for the smoothing of the wrist movements.

**Corner paths when changing the interpolation method**

Corner paths are also generated when one interpolation method is exchanged for another. The interpolation method used in the actual corner paths is chosen in such a way as to make the transition from one method to another as smooth as possible. If the corner path zones for orientation and position are not the same size, more than one interpolation method may be used in the corner path (see Figure 30).

The following figure shows an example of interpolation when changing from one interpolation method to another. Linear interpolation has been programmed between

*Continues on next page*
2 Motion and I/O programming

2.2.3 Interpolation of corner paths

Continued

p1 and p2; joint interpolation between p2 and p3; and Sing Area\Wrist interpolation between p3 and p4.

If the interpolation is changed from a normal TCP-movement to a reorientation without a TCP-movement or vice versa, no corner zone will be generated. The same will be the case if the interpolation is changed to or from an external joint movement without TCP-movement.

Interpolation when changing coordinate system

When there is a change of coordinate system in a corner path, for example a new TCP or a new work object, joint interpolation of the corner path is used. This is also applicable when changing from coordinated operation to non-coordinated operation, or vice versa.
Size reduction of programmed corner zones

If programmed positions are located close to each other, it is not unusual for the programmed zones to overlap. To get a well-defined path and to achieve optimum velocity at all times, the robot reduces the size of the zone. As default, the robot reduces the size of the zone to half the distance from one programmed position to another.

Behavior between fly-by points

Too big programmed zones result in the zones being cut off to half the distance from one overlapping programmed position to the other (see the following figure).

Both the position zone and the reorientation and additional axis zone can overlap. As soon as one of these corner path zones is too big, that zone is reduced.

Behavior between fly-by point and fine point

For a movement from a fine point to a fly-by point, the optional argument `\KeepStartPath` can be used in the move instruction. This sets a zone around the fine point in which the movement must follow the programmed path, and not enter any corner zone.

**Example:**

```
MoveL p1,v500,fine,tool1;
MoveL p2,v500 \KeepStartPath:=15,z40,tool1;
MoveL p3,v500,fine,tool1;
```

Continues on next page
For a movement from a fly-by point to a fine point, the optional argument \texttt{KeepEndPath} can be used in the move instruction. This end zone is a distance from the fine point during which the movement must follow the programmed path, so any corner zone must end before entering the end zone.

Example:

\begin{verbatim}
MoveL p1,v500,fine,tool1;
MoveL p2,v500,z30,tool1;
MoveL p3,v500 \texttt{KeepEndPath:=15,fine,tool1;}
\end{verbatim}

The \texttt{KeepStartPath} and \texttt{KeepEndPath} are specified in mm of TCP movement. While the TCP is within this zone, the tool reorientation and additional axis movement must also follow it programmed movement, and not be part of any reorientation and additional axis corner zone.
Planning time for fly-by points

Occasionally, if the next movement is not planned in time, programmed fly-by points can give rise to a stop point. This may happen when:

- A number of logical instructions with long program execution times are programmed between short movements.
- The points are very close together at high speeds.

If stop points are a problem then use concurrent program execution.

To suppress warnings from corner path failures, use the instruction CornerPathWarning.

Note

If the fly-by point is changed into a finepoint, the path after the recalculated point can also be affected.

Path when p2 is a fly-by point:

Path when p2 is a finepoint:
2.2.4 Independent axes

Description

An independent axis is an axis moving independently of other axes in the robot system. It is possible to change an axis to independent mode and later back to normal mode again.

A special set of instructions handles the independent axes. Four different move instructions specify the movement of the axis. For instance, the `IndCMove` instruction starts the axis for continuous movement. The axis then keeps moving at a constant speed (regardless of what the robot does) until a new independent-instruction is executed.

To change back to normal mode a reset instruction, `IndReset`, is used. The reset instruction can also set a new reference for the measurement system - a type of new synchronization of the axis. Once the axis is changed back to normal mode it is possible to run it as a normal axis.

Program execution

An axis is immediately change to independent mode when an `Ind_Move` instruction is executed. This takes place even if the axis is being moved at the time, such as when a previous point has been programmed as a fly-by point, or when simultaneous program execution is used.

If a new `Ind_Move` instruction is executed before the last one is finished, the new instruction immediately overrides the old one.

If a program execution is stopped when an independent axis is moving, that axis will stop. When the program is restarted the independent axis starts automatically.

No active coordination between independent and other axes in normal mode takes place.

If a loss of voltage occurs when an axis is in independent mode, the program cannot be restarted. An error message is then displayed, and the program must be started from the beginning.

Note that a mechanical unit may not be deactivated when one of its axes is in independent mode.
Stepwise execution

During stepwise execution, an independent axis is executed only when another instruction is being executed. The movement of the axis will also be stepwise in line with the execution of other instruments.

![Stepwise execution diagram](image)

Jogging

Axes in independent mode cannot be jogged. If an attempt is made to execute the axis manually, the axis does not move and an error message is displayed. Execute an `IndReset` instruction or move the program pointer to main, in order to leave the independent mode.

Working range

The physical working range is the total movement of the axis.

The logical working range is the range used by RAPID instructions and read in the jogging window.

After synchronization (updated revolution counter), the physical and logical working range coincide. By using the `IndReset` instruction the logical working area can be moved, see the following figure.

![Working range diagram](image)

The resolution of positions is decreased when moving away from logical position 0. Low resolution together with stiff tuned controller can result in unacceptable torque, noise and controller instability. Check the controller tuning and axis performance close to the working range limit at installation. Also check if the position resolution and path performance are acceptable.
2 Motion and I/O programming

2.2.4 Independent axes

Continued

Speed and acceleration

In manual mode with reduced speed, the speed is reduced to the same level as if the axis was running as non-independent. Note that the IndSpeed function will not be TRUE if the axis speed is reduced.

The VelSet instruction and speed correction in percentage via the production window, are active for independent movement. Note that correction via the production window inhibits TRUE value from the IndSpeed function.

In independent mode, the lowest value of acceleration and deceleration, specified in the configuration file, is used both for acceleration and deceleration. This value can be reduced by the ramp value in the instruction (1 - 100%). The AccSet instruction does not affect axes in independent mode.

Robot axes

Only robot axis 6 can be used as an independent axis. Normally the IndReset instruction is used only for this axis. However, the IndReset instruction can also be used for axis 4 on IRB 1600, 2600 and 4600 models (not for ID versions). If IndReset is used for robot axis 4, then axis 6 must not be in the independent mode.

If axis 6 is used as an independent axis, singularity problems may occur because the normal 6-axes coordinate transform function is still used. If a problem occurs, execute the same program with axis 6 in normal mode. Modify the points or use SingArea\Wrist or MoveJ instructions.

The axis 6 is also internally active in the path performance calculation. A result of this is that an internal movement of axis 6 can reduce the speed of the other axes in the system.

The independent working range for axis 6 is defined with axis 4 and 5 in home position. If axis 4 or 5 is out of home position the working range for axis 6 is moved due to the gear coupling. However, the position read from FlexPendant for axis 6 is compensated with the positions of axis 4 and 5 via the gear coupling.
2.2.5 Soft Servo

Description

In some applications there is a need for a servo, which acts like a mechanical spring. This means that the force from the robot on the work object will increase as a function of the distance between the programmed position (behind the work object) and the contact position (robot tool - work object).

Softness

The relationship between the position deviation and the force, is defined by a parameter called softness. The higher the softness parameter, the larger the position deviation required to obtain the same force.

The softness parameter is set in the program and it is possible to change the softness values anywhere in the program. Different softness values can be set for different joints and it is also possible to mix joints having normal servo with joints having soft servo.

Activation and deactivation of soft servo as well as changing of softness values can be made when the robot is moving. When this is done, a tuning will be made between the different servo modes and between different softness values to achieve smooth transitions. The tuning time can be set from the program with the parameter ramp. With \( \text{ramp} = 1 \), the transitions will take 0.5 seconds, and in the general case the transition time will be \( \text{ramp} \times 0.5 \) in seconds.

Note

Deactivation of soft servo should not be done when there is a force between the robot and the work object.

Note

With high softness values there is a risk that the servo position deviations may be so big that the axes will move outside the working range of the robot.
2.2.6 Stop and restart

Stopping movement

A movement can be stopped in three different ways:

- For a program stop, soft stop or quick stop, the robot will stop on the path, which makes a restart easy.
- For a halt with motors off, the mechanical brakes are used to achieve a deceleration distance, which is as short as specified for safety reasons. The path deviation will usually be bigger for a halt with motors off than for a stiff stop.

Starting movement

After a stop (any of the types above) a restart can always be made on the interrupted path. If the robot has stopped outside the programmed path, the restart will begin with a return to the position on the path, where the robot should have stopped.

A restart following a power failure is equivalent to a restart after a halt with motors off. It should be noted that the robot will always return to the path before the interrupted program operation is restarted, even in cases when the power failure occurred while a logical instruction was running. When restarting, all times are counted from the beginning; for example, positioning on time or an interruption in the instruction \texttt{WaitTime}.
2.3 Synchronization with logical instructions

Logical instructions

Instructions are normally executed sequentially in the program. Nevertheless, logical instructions can also be executed at specific positions or during an ongoing movement.

A logical instruction is any instruction that does not generate a robot movement or an additional axis movement, for example an I/O instruction.

Sequential program execution at stop points

If a positioning instruction has been programmed as a stop point, the next instruction is not executed until the robot and the additional axes have come to a standstill, that is, when the programmed position has been reached.

Sequential program execution at fly-by points

If a positioning instruction has been programmed as a fly-by point, the next logical instructions are executed some time before reaching the largest zone (for position, orientation or additional axes). See the following figures. These instructions are then executed in order.

The time at which they are executed (DT) comprises the following time components:

- The time it takes for the robot to plan the next move: approximately 0.1 seconds.
- The robot delay (servo lag) in seconds: 0-1.0 seconds depending on the velocity and the actual deceleration performance of the robot.

Continues on next page
Concurrent program execution

Concurrent program execution can be programmed using the argument \Conc in the positioning instruction. This argument is used to execute one or more logical instructions at the same time as the robot moves in order to reduce the cycle time (for example used when communicating via I/O device).

When a positioning instruction with the argument \Conc is executed, the following logical instructions are also executed (in sequence).

If the robot is not moving, or if the previous positioning instruction ended with a stop point, the logical instructions are executed as soon as the current positioning instruction starts (at the same time as the movement).

If the previous positioning instruction ends at a fly-by point, the logical instructions are executed at a given time (DT) before reaching the largest zone (for position, orientation or additional axes).

Instructions which indirectly affect movements, such as Confl and SingArea, are executed in the same way as other logical instructions. They do not, however, affect the movements ordered by previous positioning instructions.

If several positioning instructions with the argument \Conc and several logical instructions in a long sequence are mixed, logical instructions are executed directly, in the order they were programmed. This takes place at the same time as the
movement, which means that logical instructions are executed at an earlier stage on the path than they were programmed.

During concurrent program execution, the following instructions are programmed to end the sequence and subsequently re-synchronize positioning instructions and logical instructions:

- a positioning instruction to a stop point without the argument `\Conc`
- the instruction `WaitTime` or `WaitUntil` with the argument `\Inpos`.

Path synchronization

In order to synchronize process equipment (for applications such as gluing, painting and arc welding) with the robot movements, different types of path synchronization signals can be generated.

With a so-called positions event, a trig signal will be generated when the robot passes a predefined position on the path. With a time event, a signal will be generated in a predefined time before the robot stops at a stop position. Moreover, the control system also handles weave events, which generate pulses at predefined phase angles of a weave motion.

All the position synchronized signals can be achieved both before (look ahead time) and after (delay time) the time that the robot passes the predefined position. The position is defined by a programmed position and can be tuned as a path distance before the programmed position.

Typical repeat accuracy for a set of digital outputs on the path is +/- 2 ms.

In the event of a power failure and restart in a `Trigg` instruction, all trigg events will be generated once again on the remaining movement path for the `Trigg` instruction.

2.4 Robot configuration

Different types of robot configurations

It is usually possible to attain the same robot tool position and orientation in several different ways, using different sets of axis angles. We call these different robot configurations.

If, for example, a position is located approximately in the middle of a work cell, some robots can get to that position from above and below when using different axis 1 directions, as shown in the following figure where the configuration to the right is attained by rotating the arm backwards. Axis 1 is rotated 180 degrees.

![Diagram showing robot configuration with axis 1 rotated 180 degrees.](xx1100000660)

Some robots may also get to that position from above and below while using the same axis 1 direction. This is possible for robot types with extended axis 3 working range. In the following figure, two different arm configurations are used to attain same position and orientation. The axis 1 angle is the same for both configurations. The configuration on the right is attained by rotating the lower arm forward and the upper arm backwards.

![Diagram showing robot configuration with different arm angles.](xx1100000661)

This can also be achieved by turning the front part of the robot upper arm (axis 4) upside down while rotating axes 5 and 6 to the desired position and orientation. The following figure shows two different wrist configurations used to attain the same position and orientation. In the configuration in which the front part of the upper arm points upwards (lower), axis 4 has been rotated 180 degrees, axis 5...
through 180 degrees and axis 6 through 180 degrees in order to attain the configuration in which the front part of the upper arm points downwards (upper).

Specifying robot configuration

When programming a robot position, also a robot configuration is specified with confdata cf1, cf4, cf6, cfX.

The way of specifying robot configuration differs for different kinds of robot types (see Technical reference manual - RAPID Instructions, Functions and Data types - confdata, for a complete description). However, for most robot types this includes defining the appropriate quarter revolutions of axes 1, 4 and 6. For example, if axis 1 is between 0 and 90 degrees, then \( cf1 = 0 \), see the following figures.

<table>
<thead>
<tr>
<th>cf3</th>
<th>cf6</th>

</tr>
<tr>
<td>2</td>
<td>3</td>
</tr>
<tr>
<td>-4</td>
<td>-4</td>
</tr>
</tbody>
</table>

Quarter revolution for a positive joint angle

Quarter revolution for a negative joint angle

Configuration control and monitoring

To achieve a well-defined robot movement it is usually desirable to let the robot attain the same configuration during program execution as the one specified in the program. To do this, configuration control and monitoring with ConfL\On or ConfJ\On should be used. The configuration monitoring involves comparing the configuration of the programmed position with that of the robot.

During linear movement, the robot always moves to the closest possible configuration. If the configuration monitoring is active with ConfL\On, a verification is made in advance to see if it is possible to achieve the programmed configuration. If it is not possible the program is stopped. When the movement is finished (in a zone or in a finepoint), it is also verified that the robot has reached the programmed configuration. If the configuration is different the program is stopped. For a detailed description of the configuration data for a specific robot type see the data type confdata in Technical reference manual - RAPID Instructions, Functions and Data types.
During axis-by-axis movement the robot always moves to the programmed configuration when ConfJ\On is used. No supervision of the axis movements is performed when configuration control is enabled. Depending on the difference between the start point configuration and the end point configuration a large movement, of especially the wrist, can be a result. If the configuration supervision is not active, the robot moves to the specified position and orientation with the configuration that has the closest joint values compared to the start point.

When the execution of a programmed position is stopped because of a configuration error, it may often be caused by some of the following reasons:

- The position is programmed offline with a faulty configuration.
- The robot tool has been changed causing the robot to take another configuration than was programmed.
- The position is subject to an active frame operation (displacement, user, object, base).
- The correct configuration in the destination position can be found by positioning the robot near it and reading the configuration on the FlexPendant.

If the configuration parameters change because of active frame operation, the configuration check can be deactivated.

**Detailed information for ConfJ**

- **MoveJ with ConfJ\Off:**
  - The robot is moved to the programmed position, with an axis position that is closest to the axis position of the start. This means that the confdata in the instruction is not used. No configuration supervision is done.

- **MoveJ with ConfJ\On:**
  - The robot is moved to the programmed position, with an axis position such that the corresponding configuration is equal to or close to the programmed configuration in the confdata.
  - If a program displacement or path correction is active, the risk is that the programmed configuration differs from the original position. As a result the robot can perform large movements of the wrist axis to achieve the programmed configuration.

**Detailed information for ConfL**

- **MoveL with ConfL\Off:**
  - The robot is moved along a straight line to the programmed position, with an axis position that is closest to the axis position of the start. This means that the confdata in the instruction is not used and no configuration supervision is done.

- **MoveL with ConfL\On:**
  - First the end position is calculated in joints, using the programmed confdata to determine the solution. Then the joint values for the configuration axes in the end position are compared to the corresponding axes for the start position. If the new configuration data is OK compared to the start point the movement will be permitted. In other cases the robot will stop in the start position with...
an error message. For details about the allowed configuration error for different robot types, see description of confdata, *Technical reference manual - RAPID Instructions, Functions and Data types*.

- If no error was reported before the movement started the system will check the configuration again when the movement is finished. If it is not the same as the programmed configuration the program will be stopped.

2.5 Robot kinematic models

**Robot kinematics**

The position and orientation of a robot is determined from the kinematic model of its mechanical structure. The specific mechanical unit models must be defined for each installation. For standard ABB master and external robots, these models are predefined in the controller.

**Master robot**

The kinematic model of the master robot models the position and orientation of the tool of the robot relative to its base as function of the robot joint angles. The kinematic parameters specifying the arm lengths, offsets and joint attitudes, are predefined in the configuration file for each robot type.
A calibration procedure supports the definition of the base frame of the master robot relative to the world frame.

Coordination with an external robot also requires a kinematic model for the external robot. A number of predefined classes of 2 and 3 dimensional mechanical structures are supported.

The following figure shows a kinematic structure of an ORBIT 160B robot using predefined model.
Calibration procedures to define the base frame relative to the world frame are supplied for each class of structures.

Reference points on turntable for base frame calibration of an ORBIT_160B robot in the home position using predefined model.

**General kinematics**

Mechanical structures not supported by the predefined structures may be modelled by using a general kinematic model. This is possible for external robots.

Modelling is based on the Denavit-Hartenberg convention according to *Introduction to Robotics, Mechanics & Control*, by John J. Craig (Addison-Wesley 1986).

The following figure shows a kinematic structure of an ORBIT 160B robot using general kinematics model.
A calibration procedure supports the definition of the base frame of the external robot relative to the world frame.

2.6 Motion supervision/collision detection

Introduction

Motion supervision is the name of a collection of functions for high sensitivity, model-based supervision of the robot’s movements. Motion supervision includes functionality for the detection of collision, jamming, and incorrect load definition. This functionality is called collision detection (option Collision Detection).

The collision detection may trig if the data for the loads mounted on the robot are not correct. This includes load data for tools, payloads and arm loads. If the tool data or payload data are not known, the load identification functionality can be used to define it. Arm load data cannot be identified.

When the collision detection is triggered, the robot is stopped as quickly as possible. By default, the torques are reversed and the brakes are applied, but it is also possible to configure a stop that does not use the brakes.

The motion supervision is by default active only when at least one axis (including additional axes) is in motion. When all axes are standing still, the function is deactivated. This is to avoid unnecessary triggering due to external process forces. The system parameter Collision detection at standstill enables the detection of any collision even at standstill, see Technical reference manual - System parameters.

Tuning of collision detection levels

The collision detection uses a variable supervision level. At low speeds it is more sensitive than during high speeds. For this reason, no tuning of the function should be required by the user during normal operating conditions. However, it is possible to turn the function on and off and to tune the supervision levels. Separate tuning parameters are available for jogging and program execution. The different tuning parameters are described in Technical reference manual - System parameters.

There is a RAPID instruction called MotionSup which turns the function on and modifies the supervision level. This is useful in applications where external process forces act on the robot in certain parts of the cycle. The MotionSup instruction is described in Technical reference manual - RAPID Instructions, Functions and Data types.

The tune values are set in percent of the basic tuning where 100% corresponds to the basic values. Increasing the percentage gives a less sensitive system and decreasing gives the opposite effect. It is important to note that if tune values are set in the system parameters and in the RAPID instruction both values are taken into consideration. Example: If the tune value in the system parameters is set to
150% and the tune value is set to 200% in the RAPID instruction the resulting tune level will be 300%.

There is a maximum level to which the total collision detection tune level can be changed. This value is set by default to 300% but it can be modified via the system parameter `motion_sup_max_level`.

Modifying motion supervision

To modify the motion supervision, open the tasks.

1. Tap the Task list and select a task. If you have more than one task, you need to set the desired values for each task separately.
2 Tap OFF/ON to remove or activate path supervision. Tap +/- to adjust sensitivity. The sensitivity can be set between 0 and 300. Unless you have the option Collision Detection installed, path supervision only affects the robot in auto and manually full speed mode.

3 Tap OFF/ON to remove or activate jog supervision. Tap +/- to adjust sensitivity. The sensitivity can be set between 0 and 300. This setting has no effect, unless you have the option Collision Detection installed.

For more information on Collision Detection, see Application manual - Controller software OmniCore.

Digital outputs

The digital output MotSupOn is high when the collision detection function is active and low when it is not active. Note that a change in the state of the function takes effect when a motion starts. Thus, if the collision detection is active and the robot is moving, MotSupOn is high. If the robot is stopped and the function turned off, MotSupOn is still high. When the robot starts to move, MotSupOn switches to low.

The digital output MotSupTrigg goes high when the collision detection triggers. It stays high until the error code is acknowledged, either from the FlexPendant or through the digital input AckErrDialog.

The digital outputs are described in more detail in the Operating manual - OmniCore and Technical reference manual - System parameters.

Limitations

The motion supervision is only available for the robot axes. It is not available for track motions, orbit stations, or any other external manipulators.

The collision detection is deactivated when at least one axis is run in independent joint mode. This is also the case even when it is an additional axis which is run as an independent joint.

The collision detection may trigger when the robot is used in soft servo mode. Therefore, it is advisable to turn the collision detection off when the robot is in soft servo mode.

If the RAPID instruction MotionSup is used to turn off the collision detection, this will only take effect once the robot starts to move. As a result, the digital output MotSupOn may temporarily be high at program start before the robot starts to move.

The distance the robot backs up after a collision is proportional to the speed of the motion before the collision. If repeated low speed collisions occur, the robot may not back up sufficiently to relieve the stress of the collision. As a result, it may not be possible to jog the robot without the supervision triggering. In this case use the jog menu to turn off the collision detection temporarily and jog the robot away from the obstacle.

In the event of a stiff collision during program execution, it may take a few seconds before the robot starts to back up.
If the robot is mounted on a track the collision detection should be set to off when the track is moving. If it is not turned off the collision detection may trigger when the track moves, even if there is no collision.

2.7 Singularities

**Description**

Some positions in the robot working space can be attained using an infinite number of robot configurations to position and orient the tool. These positions, known as singular points (singularities), constitute a problem when calculating the robot arm angles based on the position and orientation of the tool.

Generally speaking, a robot has two types of singularities; arm singularities or wrist singularities.

Arm singularities are all configurations where the wrist center (the intersection of axes 4, 5, and 6) ends up directly above axis 1. Wrist singularities are configurations where axis 4 and axis 6 are on the same line, that is axis 5 has an angle equal to 0.

Arm singularity occurs where the wrist center and axis 1 intersect.

Wrist singularity occurs when axis 5 is at 0 degrees.
Singularity points of robots without parallel rod

Robots without parallel rod (serial link robots) have the wrist singularity and the arm singularity, and in addition, they have a third kind of singularity. This singularity occurs at robot positions where the wrist center and the rotation centers of axes 2 and 3 are all in a straight line, see the following figure.

Singularity points of serial link robots with 7 axes

Serial link robots with 7 axes, such as the IRB 14000/14050, have all the singularities of 6-axis robots but also have two additional singularities.

The first of these is when axis 2 has an angle equal to zero so that axis 1 and axis 7 are on the same line. This is similar to the wrist singularity.

The second singularity is related to the calculation of the arm angle and varies depending on which reference direction is configured, since the singularity occurs when the WCP is on the reference direction. For more information, see Arm-Angle Reference Direction in Technical reference manual - System parameters.

Program execution through singularities

During joint interpolation, problems do not occur when the robot passes singular points.

When executing a linear or circular path close to a singularity, the velocities in some joints (1 and 6/4 and 6) may be very high. In order not to exceed the maximum joint velocities, the linear path velocity is reduced.

The high joint velocities may be reduced by using the mode (SingArea\Wrist) when the wrist axes are interpolated in joint angles, while still maintaining the linear path of the robot tool. An orientation error compared to the full linear interpolation is however introduced.
Note that the robot configuration changes dramatically when the robot passes close to a singularity with linear or circular interpolation. To avoid the re-configuration, the first position on the other side of the singularity should be programmed with an orientation that makes the re-configuration unnecessary.

Also, it should be noted that the robot must not be in its singularity when only external joints are moved. This may cause robot joints to make unnecessary movements.

For robots with 7 axes or more, the robot may be able to automatically adjust the arm angle in order to avoid some singularities, see Operating manual - OmniCore.

### Jogging through singularities

During joint interpolation, problems do not occur when the robot passes singular points.

During linear interpolation, the robot cannot pass singular points. Moving close to singularities may lead to a lower TCP speed while having large joint movements.

2 Motion and I/O programming

2.8 Optimized acceleration limitation

### Description

The acceleration and speed of the robot is continuously controlled so that the defined limits are not exceeded.

The limits are defined by the user program (for example programmed speed or AccSet) or defined by the system itself (for example maximum torque in gearbox or motor, maximum torque or force in robot structure).

### Load data

As long as the load data (mass, center of gravity, and inertia) is within the limits on the load diagram and correctly entered into the tool data, then no user defined acceleration limits are needed and the service life of the robot is automatically ensured.

If the load data lies outside the limits on the load diagram, then special restrictions may be necessary, that is AccSet or lower speed, as specified on request from ABB.

### TCP acceleration

TCP acceleration and speed are controlled by the path planner with the help of a complete dynamic model of the robot arms, including the user defined loads.

The TCP acceleration and speed depends on the position, speed, and acceleration of all the axes at any instant in time and thus the actual acceleration varies continuously. In this way the optimal cycle time is obtained, that is one or more of the limits is at its maximum value at every instant. This means that the robot motors and structure are utilized to their maximum capability at all times.
2.9 World Zones

Description of World Zones

When using world zones (option World Zones), the robot stops or an output is automatically set if the robot is inside a special user-defined area. Here are some examples of applications:

- When two robots share a part of their respective work areas. The possibility of the two robots colliding can be safely eliminated by the supervision of these signals.
- When external equipment is located inside the robot’s work area. A forbidden work area can be created to prevent the robot colliding with this equipment.
- Indication that the robot is at a position where it is permissible to start program execution from a PLC.

**WARNING**

For safety reasons, this software shall not be used for protection of personnel. Use hardware protection equipment for that.

Using World Zones

Use World Zones:

- To indicate that the tool center point is in a specific part of the working area.
- To limit the working area of the robot in order to avoid collision with the tool.
- To make a common work area for two robots available to only one robot at a time.

Definition of World Zones in the world coordinate system

World Zones are defined in the world coordinate system. The sides of the boxes are parallel to the coordinate axes and the cylinder axis is parallel to the z-axis of the world coordinate system.
A World Zone can be defined to be inside or outside the shape of the box, sphere, or the cylinder.

World Zone can also be defined in joints. The zone is to be defined between (inside) or not between (outside) two joint values for any robot or additional axes.

Supervision of the robot TCP

The movement of the tool center point is supervised and not any other points on the robot.

The TCP is always supervised irrespective of the mode of operation, for example, program execution and jogging.

Stationary TCPs

If the robot is holding a work object and working on a stationary tool, a stationary TCP is used. If that tool is active, the tool will not move and if it is inside a World Zone then it is always inside.

Actions

Set a digital output when the TCP is inside a World Zone

This action sets a digital output when the TCP is inside a World Zone. It is useful to indicate that the robot has stopped in a specified area.

Continues on next page
Set a digital output before the TCP reaches a World Zone

This action sets a digital output before the TCP reaches a World Zone. It can be used to stop the robot just inside a World Zone.

Stop the robot before the TCP reaches a World Zone

A World Zone can be defined to be outside the work area. The robot will then stop with the Tool Center Point just outside the World Zone, when heading towards the Zone.

When the robot has been moved into a World Zone defined as an outside work area, for example, by releasing the brakes and manually pushing, then the only ways to get out of the Zone are by jogging or by manual pushing with the brakes released.
2 Motion and I/O programming

2.9 World Zones

Continued

Minimum size of World Zones

Supervision of the movement of the tool center points is done at discrete points with a time interval between them that depends on the path resolution. It is up to the user to make the zones large enough so the robot cannot move right through a zone without being checked inside the Zone.

Make sure that the zones are a bit larger than the minimum size.

<table>
<thead>
<tr>
<th>Speed Resol.</th>
<th>1000 mm/s</th>
<th>2000 mm/s</th>
<th>4000 mm/s</th>
</tr>
</thead>
<tbody>
<tr>

<td>320 mm</td>
</tr>
<tr>
<td>3</td>
<td>120 mm</td>
<td>240 mm</td>
<td>480 mm</td>
</tr>
</tbody>
</table>

If the same digital output is used for more than one World Zone, the distance between the Zones must exceed the minimum size, as shown in the table above, to avoid an incorrect status for the output.

It is possible that the robot can pass right through a corner of a zone without it being noticed, if the time that the robot is inside the zone is too short. Therefore, make the size of the zone larger than the dangerous area.

If World Zones are used in combination soft servo, the zone size must be additional increased to compensate for the lag from soft servo. The soft servo lag is the distance between the TCP of the robot and supervision of world zone at interpolation time. The soft servo lag will be increased with higher softness defined with the instruction SoftAct.

Maximum number of World Zones

A maximum of 20 World Zones can be defined at the same time.

Continues on next page
Power failure, restart, and run on

Stationary World Zones will be deleted at power off and must be reinserted at power on by an event routine connected to the event POWER ON.

Temporary World Zones will survive a power failure but will be erased when a new program is loaded or when a program is started from the main program (PP to Main or PP to routine).

The digital outputs for the World Zones will be updated first at Motors on. That is, when the controller is restarted the World Zone status will be set to outside during start. At first MOTORS ON after restart the World Zone status will be updated correctly.

If the robot is moved during MOTORS OFF the World Zone status will not be updated until next MOTORS ON order.

A hard emergency stop (not SoftAS, SoftGS, or SoftES) can result in an incorrect World Zone status since the robot can move in or out of a Zone during the stopping movement without the World Zone signals being updated. The World Zone signals will be correctly updated after a MOTORS ON order.

2.10 I/O principles

Description

The robot generally has one or more I/O boards. Each of the boards has several digital and/or analog channels which must be connected to logical signals before they can be used. This is carried out in the system parameters and has usually already been done using standard names before the robot is delivered. Logical signals must always be used during programming.

A physical channel can be connected to several logical signals, but can also have no logical connections, as shown in the following figure.

To be able to use an I/O board, its channels must be given logical signals. In the following figure, the physical output 2 is connected to two different logical signals. IN16, on the other hand, has no logical signal and thus cannot be used.

Signal characteristics

The characteristics of a signal are depend on the physical channel used as well as how the channel is defined in the system parameters. The physical channel determines time delays and voltage levels (see the product specification for the robot controller). The characteristics, filter times and scaling between programmed and physical values, are defined in the system parameters.

When the power supply to the robot is switched on, all signals are set to zero. They are not, however, affected by emergency stops or similar events.

An output can be set to one or zero from within the program. This can also be done using a delay or in the form of a pulse. If a pulse or a delayed change is ordered for an output, the program execution continues. The change is then carried out without affecting the rest of the program execution. If, on the other hand, a new change is ordered for the same output before the given time elapses, the first change is not carried out.

Continues on next page
The following figure shows an example where the instruction `SetDO` is not carried out at all because a new command is given before the time delay has elapsed.

Signals connected to interrupt

RAPID interrupt functions can be connected to digital signal changes. The function can be called on a raising or falling edge of the signal. However, if the digital signal changes very quickly, the interrupt can be missed.

For example, if a function is connected to a signal called `do1` and the program code is as follows:

```
SetDO do1,1;
SetDO do1,0;
```

The signal will first go to high (1) and then low (0) in a few milliseconds. In this case the interrupt may be lost. To be sure that the interrupt is not lost, make sure that the output is set before resetting it.

For example:

```
SetDO do1,1;
WaitDO do1,1;
SetDO do1,0;
```

With this method, no interrupts will be lost.

System signals

Logical signals can be interconnected by means of special system functions. If, for example, an input is connected to the system function `Start`, a program start is automatically generated as soon as this input is enabled. These system functions are generally only enabled in automatic mode.

Cross connections

Digital signals can be interconnected in such a way that they automatically affect one another:

- An output signal can be connected to one or more input or output signals.
- An input signal can be connected to one or more input or output signals.

Continues on next page
If the same signal is used in several cross connections, the value of that signal is the same as the value that was last enabled (changed).

Cross connections can be interlinked, in other words, one cross connection can affect another. They must not, however, be connected in such a way so as to form a "vicious circle", for example cross-connecting \( \text{di1} \) to \( \text{di2} \) whilst \( \text{di2} \) is cross-connected to \( \text{di1} \).

If there is a cross connection on an input signal, the corresponding physical connection is automatically disabled. Any changes to that physical channel will thus not be detected.

Pulses or delays are not transmitted over cross connections.

Logical conditions can be defined using \( \text{NOT} \), \( \text{AND} \), and \( \text{OR} \).

<table>
<thead>
<tr>
<th>Examples</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>( \text{di2} = \text{di1} ) &lt;br&gt;( \text{di3} = \text{di2} ) &lt;br&gt;( \text{do4} = \text{di2} )</td>
<td>If ( \text{di1} ) changes, then ( \text{di2} ), ( \text{di3} ), and ( \text{do4} ) will be changed to the corresponding value.</td>
</tr>
<tr>
<td>( \text{do8} = \text{do7} ) &lt;br&gt;( \text{do8} = \text{di5} )</td>
<td>If ( \text{do7} ) is set to 1, ( \text{do8} ) will also be set to 1. If ( \text{di5} ) is then set to 0, ( \text{do8} ) will also be changed (in spite of the fact that ( \text{do7} ) is still 1).</td>
</tr>
<tr>
<td>( \text{do5} = \text{di6} \text{ AND} \text{do1} )</td>
<td>( \text{do5} ) is set to 1 if both ( \text{di6} ) and ( \text{do1} ) are set to 1.</td>
</tr>
</tbody>
</table>

Limitations

A maximum of 10 signals can be pulsed at the same time and a maximum of 20 signals can be delayed at the same time.
