Continuous Power in Data Centers
Selectivity in UPS networks
Introduction

After everyone saw the effect of the COVID-19 pandemic and the importance of digitalization became crystal clear, modern society and businesses have relied on data centers like never before. This dependence in addition to the requirement for zero-downtime in data center operations, necessitate that each tiny detail of data center design becomes of the ultimate importance and has to be carefully managed.

Since the reliability of electrical distribution infrastructure in data centers is one of the key design factors to ensure this high availability due to the sensitive nature of its IT loads that need clean and continuous power supplied through a UPS, the selectivity coordination of different protective devices (upstream and downstream of the UPS) during faults plays a vital role in increasing the availability of the electrical network.
There are three main configurations of UPS systems available in the market depending on application requirements.

- Standby UPS
- Line-interactive UPS
- Double conversion UPS

Protection philosophy needs to be designed depending on the chosen type of UPS configuration. We will focus on the low voltage double conversion UPS as it is the most commonly used configuration in data centers globally.

Double conversion UPS (as the name itself indicates, conversion is twice – AC to DC and DC to AC), which guarantees total isolation through the DC bus between the output of the UPS system connected to the loads and the input that may include power quality problems.

In this configuration, the UPS might have a possibility of accepting three different sources of power:

1. The First Source is from the utility which acts as a main power source and supplies power to the battery charging source in addition to power to the load through the rectifier/inverter combination.
2. The Second source is the battery itself which provides power instantaneously during any transient event at the input side and provides bridging time till the generator starts (usually in the range of minutes).
3. The Third source is a generator which provides backup during outages (usually in the range of hours).

Static bypass switch supply power to the load normally during eco-mode, and also during abnormal conditions such as short circuit or temporary overload situations.

When temporary overloading is required due to the nature of loads, the power supply is guaranteed to the load from the network through a static bypass switch which will exclude the UPS during this phase.

Knowing the different sources of power and UPS's operating modes is imperative to dimension and implement the right protection scheme along with selecting the right protection devices.

Figure 1: Simplified diagram of Double Conversion UPS.
CONTINUOUS POWER IN DATA CENTERS

The UPS’s main function is to provide clean and continuous power to the downstream loads. If the UPS cannot provide clean energy or an adequate voltage level, as per IEC 62040-3, the UPS will transfer the load to the static bypass switch. A UPS represents an additional power source in the electrical network that has its own behavior/ characteristics, which needs to be taken into consideration during system and protection design.

In a normal operation, the UPS supplies the load from either:

1. The utility (or Generator) through the rectifier in path 1 in Figure 2.
2. The utility (or Generator) through the static bypass switch to minimize losses (Eco-mode), as shown in path 2 in Figure 2
3. Through the battery in the case of a utility outage till the generator comes online, as shown in path 3 in Figure 2

The UPS inverter capability on current delivery for downstream short circuits is limited to 2-3 times of its rated current value, while the static bypass switch is often dimensioned to carry at least 10 times of the UPS rated current for a period of 20-100 milliseconds.

During downstream load faults, the load circuit breaker is required to clear the fault as fast as possible to restore the voltage on the output bus and stay within the ITIC requirements of other connected IT loads.
Sizing considerations

The circuit breaker selection needs to take into consideration factors based on the location of the breaker in the circuit.

Below are a few factors to support the UPS network design and component selection.

The UPS input breaker (QA1) shall consider:
- The UPS rated power and overload characteristics.
- The Battery charging current.
- Must withstand the prospective short circuit from the most powerful of sources (utility transformer).
- Must trip the prospective short circuit delivered by the least powerful of sources (typically the generator).

The static bypass switch input breaker (QA2) shall consider:
- The same rules for short circuit withstand for QA1 in relation to different power sources apply as well to QA2.
- Shall withstand the simultaneous energizing of all loads.
- Shall limit the let-throw energy below the thyristor I²t value.

Downstream Load breakers (QA3)
- The breakers shall be sized for the load needs and to trip and clear short circuits as fast as possible.
- The breakers should be selective with the upstream circuit breakers (will be discussed in the next section).

Figure 3: Example of a downstream fault
Sizing considerations

Selectivity is defined in IEC 60947-2 “Low voltage Equipment – part 2: Circuit breakers”, and we can accordingly explain it as the selectivity during a fault between two protection devices (i.e., circuit breakers) connected in a series, where the protection device closer to the fault would trip without tripping the upstream protection devices.

This is mainly achieved to isolate the fault and maintain the supply for other circuits that are not directly connected to the fault, and if selectivity is not achieved between circuit breakers, the purpose of installing an expensive UPS system is defeated.

There are two types of selectivity: “Total selectivity”, where the selectivity is achieved for all the short circuit current values up to the maximum capacity of the downstream breaker, and “Partial selectivity”, which is achieved only up to a certain level before the upstream breaker trips.

Now, let’s take an example assuming a downstream fault. As shown in Figure 3, the UPS will be transferred to a static transfer switch to supply the fault current as explained earlier. It is definitely required that you trip the QA3 circuit breaker and isolate the faulty section before tripping QA2 and dropping the entire load supplied by the UPS. It is also important to isolate the fault as quickly as possible to restore the output voltage for the load bus supplied by UPS.

ABB provides selectivity tables through the SOC tool to define the selectivity between its different products, as shown in the Figure 4 extract. Here, for example, if the load downstream was protected by a MCB S803 B 63, the upstream breaker could be Tmax XT2 100 A, which provides partial selectivity up to 4.5 kA only, or 160A, which provides total selectivity.
ABB has created standard building blocks for data centers to speed up the design phase, taking into consideration the related breaker sizing considerations and selectivity based on the UPS, and bypass characteristics for different UPS power ratings, including maximum input current, overload capability, short circuit, and selectivity.

DC Breaker Selection

Are you searching for a way to protect the UPS’s battery cabinet? This tool will also guide you through the selection of a DC breaker, which is fundamental to protect the battery cabinet in case of a fault in between the cabinet and the inverter inside the UPS.

The Energy storage connected to a UPS consists of battery strings in parallel. Each string has its own disconnection/protection method, such as switch disconnector, MCB, MCCB or a fuse, depending on its rating. The parallel strings are then connected to the UPS either through a switch disconnector (if the protection was already provided by a fuse or circuit breaker on a string level), or a DC circuit breaker to provide DC protection in the paralleling switchgear at the point of UPS connection. The DC breakers should be at least enter in either DC-21 or DC-22 categories and should provide bi-directional power flow capability.

To quickly isolate the DC side of the UPS in case of an electrical fault and avoid affecting the reliability and integrity of the Data Center electrical infrastructure, ABB has a wide range of solution blocks for the UPS’s DC section, based on the below notes for sizing.

Notes for sizing

- DC side isolated from ground
- Maximum breaking capacity to be selected according to the prospective short circuit current for different installation
- Circuit breaker size has been selected considering maximum voltage and maximum discharge current
- Probability of fault occurring between the batteries and DC circuit breaker is not considered, and the circuit breaker shall be installed as close as possible to the batteries.
- Ambient temperature up to +40°C
- Maximum discharge current refers to 1.7V/cell as battery cut off voltage
- Always refer to UPS technical data sheets for details on number of blocks vs autonomy and temperature
